Product List Page

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product List Page provides a centralized view for users to manage and browse the company's product catalog. It allows users to view key product information in a structured table, search for specific items using filters, and easily navigate to detailed product records or create new entries.

1.2 Step-by-Step Flow

1. Initial Load: When the page is first opened, the system automatically retrieves the full list of products and displays them in the table.
2. Filtering: Users can refine the list by entering search terms or selecting a specific brand from the filter bar.
3. Applying Search: After adjusting the filters, the user clicks the "Apply Search" button to refresh the table with the relevant results.
4. Viewing Details: Users can click on a product name within the table to be redirected to a dedicated page containing full details for that specific item.
5. Adding Products: A dedicated button is available to quickly transition the user to the "Add Product" page to create new catalog entries.

1.3 Key Concepts

- Filter Bar: A set of controls at the top of the page that allows users to narrow down the product list based on specific criteria like name or brand.
- Product Table: The main display area that organizes product data (such as SKU, Name, Brand, Code, Tax, and Price) into rows and columns for easy comparison.
- Pagination: A system that breaks the product list into manageable chunks (pages) to ensure the page remains fast and easy to navigate.
- Hypertext Links: Clickable text within the product name column that acts as a shortcut to view more in-depth information about a specific product.

1.4 Business Value

- Efficiency: Enables staff to quickly locate specific inventory items without manually scanning the entire catalog.
- Data Accuracy: Provides a clear, consistent view of essential product metrics like pricing and tax rates, ensuring users have the information they need to make informed decisions.
-

Workflow Integration: Streamlines the product management process by providing direct access to both detailed product views and the creation of new inventory items from a single screen.

2. Logic

2.1 Overview

The Product List Page feature allows users to efficiently browse, search, and filter the company’s product catalog. By providing a structured view of all available items, this feature enables staff to quickly locate specific products based on their name or brand, while managing large volumes of data through organized pages.

2.2 Step-by-Step Flow

1. Initialization: When the user opens the Product List Page, the system automatically requests the initial set of products from the database.
2. Applying Filters: The user can narrow down the list by entering a search term or selecting a specific brand.
3. Requesting Data: Once the user clicks the "Apply Search" button, the system sends the chosen filters and the current page number to the server.
4. Data Retrieval: The system fetches the relevant product information, including details like the SKU, product name, brand, code, tax, and price.
5. Display: The system organizes this information into the product list view, ensuring the user sees only the items that match their criteria.

2.3 Key Concepts

- Pagination: A method of breaking a large list of products into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down the product list by specific criteria, such as brand name or keyword searches.
- Product Attributes: The specific details displayed for each item, including its unique identifier (SKU), name, brand, internal code, tax rate, and price.

2.4 Business Value

This feature streamlines inventory management and product lookup tasks. By allowing users to filter and paginate through the catalog, it reduces the time spent searching for specific items, minimizes manual effort, and ensures that staff are always working with accurate, up-to-date product information.

3. Data

3.1 Overview

The Product List Page feature provides a centralized view for users to browse the company's entire product catalog. It is designed to help users quickly locate specific items by offering flexible search and filtering capabilities, while ensuring the system remains fast and responsive by displaying products in manageable, bite-sized chunks.

3.2 Step-by-Step Flow

1. Requesting Data: When you open the product list, the system prepares to fetch the product catalog.
2. Applying Filters: If you enter a search term (such as a product name or SKU) or select a specific brand, the system narrows down the results to match your criteria.
3. Organizing Results: The system sorts all matching products alphabetically by their name to ensure a consistent and predictable view.
4. Pagination: To keep the page loading quickly, the system displays only a set number of products at a time. It calculates which "page" of results you are viewing and skips over the items that belong on previous pages.
5. Displaying Information: The system retrieves the relevant details for each product—including its name, SKU, brand, code, tax rate, and price—and presents them clearly on your screen.

3.3 Key Concepts

- Search: A tool that allows you to find products by typing in a name or a specific stock-keeping unit (SKU).
- Filtering: A way to isolate products by selecting a specific brand, removing unrelated items from your view.
- Pagination: A method of breaking a large list of products into smaller, numbered pages to improve performance and readability.
- Mapping: The process of taking raw data from our internal database and translating it into a clean, easy-to-read format for the user interface.

3.4 Business Value

This feature improves operational efficiency by allowing staff to quickly find and verify product information without manually scrolling through thousands of records. By providing robust search and filter tools, the system reduces the time spent on administrative tasks and ensures that users can access accurate pricing and tax information instantly, supporting better decision-making and faster customer service.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Detail Page is a centralized, read-only view designed to provide a comprehensive snapshot of a single product's information. It allows users to quickly review essential data—ranging from core identity and pricing to tax, warranty, and inventory settings—without the ability to modify the information directly on this screen.

1.2 Step-by-Step Flow

1. Page Initialization: When you navigate to the page, the system automatically requests the specific product details from the database using the product's unique identifier.
2. Data Loading: While the system retrieves the information, a loading indicator is displayed to ensure a smooth user experience.
3. Information Display: Once the data is retrieved, the page populates a two-column layout with organized "cards."
   - Left Column: Displays core details (SKU, name, description), tax information, various pricing tiers (Company, Store, External), and tracking/bundle status.
   - Right Column: Displays administrative and logistical data, including audit changes, custom attributes, physical dimensions, product schedules, barcode settings, and customer-facing policies like warranty, returns, and trade-in values.
4. Navigation & Interaction: Users can utilize the header navigation to return to the product list or access related sub-menus (such as purchase history or warehouse stock) to view further details.

1.3 Key Concepts

- Read-Only View: The page is designed strictly for viewing information; no data can be edited or saved directly from this screen.
- SKU (Stock Keeping Unit): The unique identifier for the product, which can be easily copied to the clipboard for quick reference or use in other systems.
- Sticky Navigation: The header and product identity bar (showing the SKU and Name) remain fixed at the top of the screen, ensuring that key product information is always visible even when scrolling through long lists of data.
- Pricing Tiers: The page breaks down pricing into specific categories (Company, Store, and External/MRP) to provide clarity on costs and retail expectations.
- Audit Trail: The "Changes" card provides a record of updates, helping users track the history of the product information.

1.4 Business Value

This feature serves as a "single source of truth" for product information, reducing the time staff spend searching for data across different systems. By organizing complex product data into a clean, readable, and consistent layout, it enables faster decision-making for inventory management, pricing strategy, and customer service inquiries. The inclusion of audit trails and clear policy information (like warranty and returns) also improves operational transparency and accountability.

BUSINESS REQUIREMENTS DOCUMENT

Purchase History

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Purchase History feature provides a centralized view of all procurement activity for a specific product. It allows users to track where items were sourced, how much was purchased, and the associated costs. The interface is designed to help users quickly identify transaction trends and access detailed shipment documentation.

1.2 Step-by-Step Flow

1. Automatic Loading: When you open the page for a specific product, the system automatically retrieves and displays the complete purchase history for that item.
2. Filtering: You can narrow down the list of purchases by selecting a specific supplier from the dropdown menu.
3. Search Execution: After selecting a supplier, clicking the "Search" button refreshes the table to show only the records relevant to your choice.
4. Reviewing Details: The table displays key information for each transaction, including the delivery document number, supplier name, quantity, unit price, and the date of the purchase.
5. Accessing Documents: You can click on any document number link to navigate directly to the full details of that specific shipment.
6. Quick Actions: At any time, you can use the "QR Code" or "Barcode" buttons to display or print product identification labels for scanning purposes.

1.3 Key Concepts

- Purchase Delivery Document: A unique reference number for a shipment that acts as a link to deeper, more granular information about that specific transaction.
- Supplier Filter: A tool that allows you to isolate purchase records by the vendor, making it easier to audit or review specific business relationships.
- Sorting: The ability to organize the purchase list by date, helping you view the most recent or oldest transactions first.
- Product Identification: Built-in access to QR codes and barcodes, which simplifies inventory management and physical product tracking.

1.4 Business Value

This feature improves operational efficiency by providing a "single source of truth" for product procurement. By consolidating supplier data, pricing, and delivery history into one view, users can quickly verify supply chain

consistency, audit past costs, and easily retrieve shipment documentation without searching through physical files or separate systems.

2. Logic

2.1 Overview

The Purchase History feature provides a clear, automated view of every time a specific product has been purchased. When you open a product page, the system instantly retrieves and displays a comprehensive list of past procurement records, allowing you to see exactly when, from whom, and at what price the item was acquired.

2.2 Step-by-Step Flow

1. Automatic Trigger: As soon as you navigate to a product page, the system automatically identifies the product and requests its specific purchase history.
2. Validation: The system confirms that a valid product is selected to ensure the correct data is retrieved.
3. Data Retrieval: The system searches the database for all records associated with that product.
4. Organization: The records are automatically sorted so that the most recent purchases appear at the top of the list.
5. Display: The compiled list—including supplier details, quantities, pricing, and dates—is presented to you in a table format on the screen.

2.3 Key Concepts

- Purchase Record: A single entry documenting a specific transaction, including the supplier, the amount bought, the cost per unit, and the date of the purchase.
- Automated Loading: The feature functions without manual input; the history is fetched and displayed immediately upon viewing the product.
- Chronological Sorting: The list is organized by date, ensuring the most relevant and recent information is always the first thing you see.

2.4 Business Value

This feature improves inventory management and procurement oversight by providing instant visibility into supply trends. By having immediate access to historical pricing and supplier performance for every product, your team can make more informed purchasing decisions, negotiate better rates, and quickly track the lifecycle of your inventory without needing to search through manual logs or external reports.

3. Data

3.1 Overview

The Purchase History feature provides a clear, organized view of all procurement activity for a specific product. By navigating to a product's details, users can instantly see a comprehensive list of every time that item was purchased, including details about the supplier, the quantity ordered, the cost, and when the transaction occurred.

3.2 Step-by-Step Flow

1. Request Initiation: When you open the Purchase History page for a specific product, the system automatically identifies which product you are viewing.
2. Validation: The system confirms that the selected product exists in the database. If the product cannot be found, an error message is displayed.
3. Data Retrieval: The system searches the purchase records and filters them to include only those associated with the specific product ID.
4. Sorting: The retrieved records are automatically organized by date, with the most recent purchases appearing at the top of the list.
5. Display: The final list of purchase records is presented in a table format for easy review.

3.3 Key Concepts

- Purchase Record: A single entry documenting a specific transaction, containing details such as the supplier name, quantity, price, and date.
- Product ID: A unique identifier used by the system to ensure that the purchase history displayed matches the exact product you are currently viewing.
- Chronological Sorting: The method of organizing data by date, ensuring that the most relevant and recent information is prioritized for the user.

3.4 Business Value

This feature improves inventory transparency and decision-making by allowing staff to quickly audit supply trends. By having immediate access to supplier names, historical pricing, and order volumes, the business can better track spending patterns, evaluate supplier performance, and make more informed decisions regarding future reordering.

BUSINESS REQUIREMENTS DOCUMENT

Warehouse Stocks

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Warehouse Stocks feature provides a centralized view of inventory levels for a specific product across all warehouse locations. It allows users to monitor stock availability, track costs, and manage reorder thresholds (minimum and maximum stock levels) directly within the system.

1.2 Step-by-Step Flow

1. Data Loading: When the page opens, the system automatically retrieves the stock information for the selected product from all warehouses.
2. Summary View: A summary bar at the top displays the total quantity of the product currently held across the entire organization.
3. Filtering: Users can narrow down the list of warehouses using the filter bar (by specific warehouse, name, or code). Clicking the "Search" button applies these filters to the table.
4. Reviewing Details: The table displays comprehensive data for each warehouse, including current stock, available stock, reserved units, items in transit, and financial data (average and total costs).
5. Adjusting Thresholds: Users can click the "Edit" button to enable bulk editing. This allows them to update the "Min Qty" and "Max Qty" for multiple warehouses simultaneously.
6. Validation: As changes are made to the minimum or maximum levels, the system automatically ensures that the minimum quantity does not exceed the maximum quantity, preventing invalid stock settings.

1.3 Key Concepts

- Inventory Quantity: The total amount of a product currently held in a specific warehouse.
- Available Quantity: The portion of stock that is free to be allocated to new orders (excludes reserved items).
- Reserved Quantity: Stock that has already been committed to existing orders and is not available for new sales.
- In Transit: Stock that is currently being moved to a warehouse but has not yet been officially received into the inventory.
- Min/Max Qty: Thresholds used to manage stock levels; the system uses these to help identify when a product needs to be reordered or if a warehouse is overstocked.
- Bulk Editing: A feature that allows users to modify multiple rows of data at once rather than updating each warehouse entry individually.

1.4 Business Value

This feature improves inventory accuracy and operational efficiency by providing real-time visibility into stock distribution. By allowing users to set and adjust minimum and maximum stock levels, the business can better automate reordering processes, reduce the risk of stockouts, and prevent over-accumulation of inventory, ultimately optimizing capital tied up in warehouse stock.

2. Logic

2.1 Overview

The Warehouse Stocks feature provides a comprehensive view of how a specific product is distributed across your various warehouse locations. It allows users to see not just the total quantity on hand, but also detailed breakdowns of stock status (such as reserved or in-transit items) and financial valuation per location.

2.2 Step-by-Step Flow

1. Data Retrieval: When you view a product, the system automatically pulls all stock records associated with that specific item from all connected warehouses.
2. Processing & Calculation: The system organizes this data into a clear list. For each warehouse, it calculates the "Total Cost" by multiplying the current inventory quantity by the average cost of the item.
3. Summary Generation: The system calculates a grand total of the inventory quantity across all warehouses to provide an immediate high-level view of the product's availability.
4. Display: The final information is presented in a table format, showing both the granular details for each warehouse and the overall summary totals.

2.3 Key Concepts

- Inventory Quantity: The total amount of a product currently physically present in a specific warehouse.
- Available Quantity: The portion of stock that is not reserved and is ready for immediate sale or use.
- Reserved Quantity: Stock that has been set aside for specific orders or commitments and is not available for general use.
- In-Transit Quantity: Stock that is currently being moved between locations and has not yet arrived at the destination warehouse.
- Min/Max Quantity: The defined threshold levels for stock; these help identify if a warehouse is understocked or overstocked.
- Average Cost: The calculated mean cost of the product units, used to determine the financial value of the stock on hand.

2.4 Business Value

This feature improves inventory visibility and decision-making by:

* Reducing Stockouts: By displaying "Min/Max" levels, staff can quickly identify which warehouses need replenishment.

* Improving Financial Accuracy: Providing the "Total Cost" per warehouse allows for better financial reporting and valuation of assets.

* Streamlining Operations: By distinguishing between "Available" and "Reserved" stock, the team can make more accurate promises to customers regarding delivery times and order fulfillment.

3. Data

3.1 Overview

The Warehouse Stocks feature provides a comprehensive view of inventory levels for a specific product across all your warehouse locations. It allows you to see exactly how much stock is on hand, reserved, or currently in transit, helping you maintain optimal inventory levels and make informed purchasing or distribution decisions.

3.2 Step-by-Step Flow

1. Request: You select a specific product to view its stock distribution.
2. Data Retrieval: The system gathers all inventory records associated with that product from every warehouse where it is stored.
3. Calculation: The system calculates the total value of the stock in each warehouse (based on average cost) and sums up the total inventory quantity across all locations.
4. Display: The information is presented in a clear table format, showing individual warehouse details alongside a summary footer that displays the total quantity of the product currently held in the company.

3.3 Key Concepts

- Inventory Quantity: The total amount of physical stock currently held in a specific warehouse.
- Available Quantity: The stock that is ready to be sold or used, excluding items that are already reserved.
- Reserved Quantity: Stock that has been set aside for existing orders or specific commitments.
- In-Transit Quantity: Stock that is currently being moved between locations and is not yet available for use.
- Min/Max Quantity: The defined thresholds for stock levels used to trigger reordering or prevent overstocking.
- Average Cost: The calculated mean cost of the product units, used to determine the total financial value of the stock on hand.

3.4 Business Value

This feature provides real-time visibility into your supply chain, enabling you to:

* Improve Accuracy: Eliminate guesswork by seeing exactly where your products are located.

* Optimize Stock Levels: Use the minimum and maximum quantity indicators to prevent stockouts or excess inventory.

* Financial Oversight: Instantly view the total cost of inventory per warehouse, assisting with budget management and asset valuation.

* Streamline Operations: Quickly identify which warehouses have available stock versus those that are waiting on transit, allowing for faster fulfillment decisions.

BUSINESS REQUIREMENTS DOCUMENT

Products Menu

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Products Menu is a navigation component designed to help users easily access various areas of the ERP system. It features a clean, organized layout that groups related product management tasks under a single "Products" header. By using an expandable menu style, the interface keeps the workspace uncluttered while ensuring that essential tools like inventory, categories, and pricing are always just one click away.

1.2 Step-by-Step Flow

1. Initial View: When the user first accesses the ERP, the "Products" menu is visible and set as the active navigation item.
2. Sub-menu Visibility: Because the "Products" item contains additional options, it displays a chevron icon, and the sub-menu (containing Inventory, Categories, and Pricing) is expanded by default.
3. Interaction: When a user clicks on the "Products" header, the system toggles the sub-menu, allowing the user to hide or show the list of options as needed.
4. Navigation: If a user selects a specific item within the sub-menu, the system updates the active state to reflect the current selection and routes the user to the corresponding page.

1.3 Key Concepts

- Accordion Menu: A design pattern that allows a section of content to be expanded or collapsed, helping to save screen space.
- Active State: A visual indicator that highlights which section of the menu the user is currently viewing, providing clear context within the application.
- Chevron Icon: A small arrow symbol that indicates whether a menu item can be expanded or collapsed, providing a visual cue for interactive elements.
- Navigation Routing: The process of moving the user to a specific page or view within the ERP system based on their menu selection.

1.4 Business Value

- Improved Usability: By grouping related tasks under a single "Products" menu, users can find what they need faster without navigating through multiple screens.
- Efficient Screen Real Estate: The expandable menu design ensures that the interface remains clean and focused, showing only the necessary options when the user needs them.
- Consistent User Experience: Providing a clear, predictable navigation structure helps users build familiarity with the ERP system, reducing training time and potential errors.

BUSINESS REQUIREMENTS DOCUMENT

Main Menu

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Main Header is the primary navigation bar located at the top of every page in the ERP system. It serves as the central hub for users to search for information, navigate between core business areas (Dashboard, Products, and Sales), manage personal account settings, and view system notifications.

1.2 Step-by-Step Flow

1. Search: Users can type into the search bar. The system waits for the user to finish typing before automatically triggering a search to find relevant data.
2. Navigation:

- Clicking Dashboard updates the active view to the main dashboard.
- Clicking Products opens a dropdown menu providing quick access to Inventory, Categories, and Suppliers.
- Clicking Sales immediately redirects the user to the Sales list page.

3. Notifications: Clicking the bell icon toggles a dropdown menu that displays current alerts or notifications.
4. Profile Management: Clicking the user avatar toggles a profile menu, allowing the user to access account-specific settings or sign-out options.

1.3 Key Concepts

- Debouncing: A performance feature for the search bar that waits for a brief pause in typing before processing the request, ensuring the system doesn't get overwhelmed by unnecessary searches.
- Active Tab State: A background tracker that remembers which section of the ERP the user is currently viewing to ensure the interface remains consistent.
- Conditional Menus: Dropdown panels (for Products, Notifications, and Profile) that only appear when specifically requested by the user, keeping the interface clean and uncluttered.

1.4 Business Value

- Efficiency: Provides "one-click" access to critical business modules like Sales and Inventory, reducing the time users spend navigating the system.
- Improved User Experience: By using intuitive patterns like notification bells and profile avatars, the system feels familiar and easy to learn for new users.
- Performance: The search feature is optimized to be responsive without slowing down the system, ensuring a smooth experience even when searching through large amounts of ERP data.

BUSINESS REQUIREMENTS DOCUMENT

Products Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Products Sub Menu is a navigation component designed to help users easily switch between different product-related views within the ERP system. It uses an "accordion" style, which allows users to expand or collapse the menu to keep the interface clean and organized. By default, the menu is open and highlights the main "Products" section, ensuring users land on the most relevant page immediately upon accessing the module.

1.2 Step-by-Step Flow

1. Initial Load: When the user accesses the Products section, the menu is expanded by default, and the "Products" option is automatically selected as the active page.
2. Toggle Visibility: The user can click the "Products Menu" header at any time to collapse or expand the list of options, helping them manage screen space.
3. Navigation: When the user clicks on a specific item (either "Products" or "Service Products"), the system navigates them to the corresponding page.
4. Visual Feedback: Once an item is clicked, the menu updates the visual highlight to indicate which section is currently active, providing clear context to the user.

1.3 Key Concepts

- Accordion Menu: A vertical list of items that can be hidden or shown by clicking a header, which helps reduce visual clutter.
- Active State: A visual indicator (such as a highlight or border) that shows the user which page they are currently viewing.
- Default Selection: The pre-configured setting that ensures the system starts on the most frequently used page ("Products") without requiring extra clicks.

1.4 Business Value

- Improved User Experience: By organizing navigation into a collapsible menu, the interface remains clean and intuitive, reducing the cognitive load on the user.
- Efficiency: The default selection of the "Products" page ensures that users spend less time clicking through menus to reach their primary workspace.
- Clear Orientation: The active state highlighting ensures users always know exactly where they are within the ERP system, reducing navigation errors and confusion.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Header

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Detail Header is the primary information bar located at the top of a product's page. It provides an immediate snapshot of the product's identity and pricing, while offering quick-access controls to manage that product directly from the screen.

1.2 Step-by-Step Flow

1. Display Information: The system retrieves the product's name, unique identification code (SKU), and current price, displaying them clearly at the top of the page.
2. User Interaction: The user views the product details and decides whether to modify or remove the item using the action buttons on the right side of the header.
3. Edit Action: If the user clicks "Edit," the system initiates the process to open the product's information for updates.
4. Delete Action: If the user clicks "Delete," the system prompts the user to confirm the action before proceeding with the removal of the product from the system.

1.3 Key Concepts

- Product Identity: The core details (Name and SKU) that uniquely identify an item within the catalog.
- Pricing: The current monetary value assigned to the product, displayed for quick reference.
- Action Buttons: Dedicated controls that allow users to perform administrative tasks (Edit or Delete) without navigating away from the product view.
- Confirmation Prompt: A safety mechanism triggered during the deletion process to prevent accidental removal of product data.

1.4 Business Value

This feature streamlines inventory management by centralizing essential product information and administrative controls in one location. By providing immediate access to edit and delete functions, it reduces the number of clicks required for routine maintenance, allowing staff to manage the product catalog more efficiently and accurately.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for authorized users to retrieve a list of all products stored in the ERP system. To ensure the system remains fast and easy to navigate, the product list is delivered in manageable "pages" rather than all at once. The response includes the product details (such as name, price, and stock levels) along with helpful summary information about the total number of items available.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the person requesting the data is authorized to access it. If they are not, the request is denied.
2. Parameter Validation: The system checks the requested page number and the number of items per page. If the numbers provided are invalid (e.g., negative numbers), the system alerts the user to correct them.
3. Data Retrieval: The system calculates which specific products belong on the requested page and fetches them from the database, starting with the most recently created items. It also counts the total number of products in the system.
4. Response Delivery: The system sends back the requested list of products, along with metadata confirming the current page, the limit applied, and the total count of products available.
5. Error Handling: If an unexpected technical issue occurs during this process, the system catches the error and provides a notification that the request could not be completed.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.
- Authentication: A security step that ensures only verified users can access sensitive business data.
- Metadata: Additional information provided with the product list—such as the total count of items—that helps the user understand the scope of the data they are viewing.
- Query Parameters: Specific settings (like "page" or "limit") that a user can include in their request to customize exactly which portion of the data they want to see.

1.4 Business Value

This feature enables efficient inventory management by allowing staff to browse the product catalog without overwhelming the system. By using pagination, the application remains responsive even as the product database grows, ensuring that users can quickly find and review product information without performance delays.

2. Data

2.1 Overview

This feature provides a way for external systems to retrieve a comprehensive list of products stored in our ERP database. To ensure the system remains fast and responsive even as our product catalog grows, the feature includes "pagination," which allows users to request products in smaller, manageable chunks rather than loading the entire database at once.

2.2 Step-by-Step Flow

1. Request: The system receives a request for a list of products, including specific instructions on which "page" of results to show and how many items should appear on that page.
2. Calculation: The system calculates exactly which records to retrieve based on the requested page number and the limit provided.
3. Counting: The system checks the total number of products currently in the database to help the user understand the full scope of the catalog.
4. Retrieval: The system fetches the specific batch of products, sorted by the most recently added items first.
5. Response: The system sends back the requested list of products along with helpful summary information, such as the current page number and the total count of all available products.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.
- Metadata: Additional information provided with the product list (such as the total number of items) that helps the user navigate the data effectively.
- Sorting: The process of organizing the product list so that the newest items appear at the top.
- API Endpoint: A digital gateway that allows other software to securely request and receive product information from our database.

2.4 Business Value

- Improved Performance: By loading data in smaller batches, the application remains fast and avoids overwhelming the user or the system with too much information at once.
- Better User Experience: Providing clear metadata (like total counts) allows for better navigation and interface design, such as building "Next" or "Previous" buttons in a dashboard.
-

Data Accuracy: Ensures that any system integrated with our ERP always has access to the most up-to-date product information, including current pricing and stock levels.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products?utf8= &q[attribute_predicate]=value&...&page_rows=

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Product Search API allows users to retrieve a filtered list of products from the catalog. It provides a flexible way to search for items based on specific identifiers (like SKU or product code), categories (like brand or tax status), or custom descriptive fields. The system ensures that only authorized users can access this data and validates that all search criteria exist in the system before returning results.

1.2 Step-by-Step Flow

1. Authentication & Authorization Check: The system first verifies that the user is logged in and has the necessary permissions to view the product list.
2. Parameter Extraction: The system collects all search criteria provided in the request, such as text-based filters (name, SKU), category IDs (brand, type, tax), and custom information fields.
3. Validation: The system checks that any specific IDs provided (such as a brand or tag ID) actually exist in the database. If an ID is invalid, the request is rejected.
4. Query Construction: The system builds a search query based on the provided filters, applying partial matches for text fields and exact matches for IDs.
5. Sorting & Pagination: The system applies the requested sort order and limits the number of results returned based on the user's preference.
6. Response: The system returns the matching product data or provides an appropriate error message if the request could not be processed.

1.3 Key Concepts

- Filtering: The ability to narrow down a large list of products by specific attributes like brand, tax category, or custom information fields.
- Partial Matching: A search method where the system finds products that contain the provided text, rather than requiring an exact match (e.g., searching "Apple" will return "Apple iPhone").
- Pagination: A feature that limits the number of items returned in a single request, which helps keep the system fast and easy to manage.
- Validation: A safety check that ensures the search criteria are logical and that any referenced categories or tags exist before attempting to search.

1.4 Business Value

This feature empowers users to quickly locate specific products within a large inventory without needing to browse manually. By supporting a wide range of search parameters—from technical codes to custom descriptive fields—it provides the flexibility needed for various business workflows, such as inventory management, sales reporting, or customer support inquiries. The built-in security and validation ensure that data remains protected and that search results are always accurate.

2. Data

2.1 Overview

The Product Search API allows users to retrieve a filtered list of products from the system. It provides a flexible way to search the catalog by combining various criteria—such as names, codes, brands, tax categories, and custom tags—into a single request. The feature is designed to handle large datasets by allowing users to specify how many results to display at once and how to sort them.

2.2 Step-by-Step Flow

1. Receive Request: The system receives a search request containing various filter criteria (e.g., SKU, name, brand, or tags) and a limit for the number of results.
2. Apply Text Filters: The system searches for products where specific fields (like name, SKU, or product code) contain the text provided by the user.
3. Apply Category Filters: The system filters products based on exact matches for categories like Brand, Product Type, or Tax ID. It verifies that these categories actually exist in the system before proceeding.
4. Apply Tag Filters: If tags are provided, the system narrows the results to only include products associated with those specific tags.
5. Sort Results: The system organizes the final list based on the user's preferred sorting instructions (e.g., by name in alphabetical order).
6. Limit Results: The system applies the requested page limit to ensure the response size is manageable.
7. Return Data: The system returns the filtered list of products or provides an error message if the request was invalid, unauthorized, or if a referenced category (like a brand) could not be found.

2.3 Key Concepts

- Filters: Criteria used to narrow down the product list, such as searching for a partial name or an exact brand ID.
- Validation: A safety check performed by the system to ensure that requested categories (like a specific Brand ID) exist before attempting to filter by them.

- Tagging: A way to group products together; the search allows you to find all products that share one or more specific tags.
- Sorting: The ability to arrange the search results in a specific order, such as ascending or descending.
- Pagination: A method to control the number of items returned in a single response, which helps keep the application fast and responsive.

2.4 Business Value

This feature empowers users to quickly locate specific items within a large product catalog without manual browsing. By supporting multiple search criteria, it enables complex reporting and inventory management tasks. Furthermore, the built-in validation and pagination ensure that the system remains stable and provides accurate, high-quality data to the user, even when dealing with extensive product lists.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	October 20, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve detailed information about a specific product from our system. By providing a unique product identifier, users can access a standardized summary of that product, including its name, pricing, stock-keeping unit (SKU), and description. The system is designed to handle requests securely and provide clear feedback if a product cannot be found or if there is an issue with the request.

1.2 Step-by-Step Flow

1. Input Validation: The system checks that the provided product ID is formatted correctly. If the format is invalid, the system rejects the request.
2. Authentication Check: The system verifies that the user has the necessary permissions to access product data. If the user is not logged in or lacks authorization, the request is denied.
3. Data Retrieval: The system searches the database for a product matching the provided ID.
4. Response Delivery: If the product is found, the system returns the full product details in a consistent, pre-defined format. If no product matches the ID, the system notifies the user that it could not be found.
5. Error Handling: If an unexpected technical issue occurs during the process, the system logs the error and provides a general notification that a server-side problem occurred.

1.3 Key Concepts

- Product ID: A unique identifier used to pinpoint a specific item in our inventory.
- Standardized Schema: A consistent structure for data, ensuring that every product retrieved looks the same and contains the same types of information.
- Authentication: A security step that ensures only verified users can access sensitive product information.
- Error Codes: Standardized messages that help identify why a request failed (e.g., "Not Found" if the ID doesn't exist, or "Unauthorized" if access is restricted).

1.4 Business Value

This feature is essential for enabling seamless integration between our ERP system and other business tools. By providing a reliable, standardized way to fetch individual product details, we ensure that sales, inventory, and customer service teams always have access to accurate, up-to-date product information. This reduces manual data entry, minimizes errors, and improves the overall efficiency of our product management workflows.

2. Data

2.1 Overview

This feature provides a way to retrieve detailed information about a specific product from our system. By using a unique product identifier, users can request a single product record, which will return all relevant details such as the product name, SKU, price, description, and creation date.

2.2 Step-by-Step Flow

1. Validation: The system first checks if the provided product ID is formatted correctly. If the format is invalid, the request is rejected immediately.
2. Database Lookup: Once the ID is confirmed as valid, the system searches the database for a matching product record.
3. Result Handling:

* If a matching product is found, the system returns the full product details.

* If no product exists for that ID, the system reports that the requested resource could not be found.

4. Error Management: Throughout the process, the system is designed to handle potential issues—such as missing authentication or unexpected server errors—by providing clear, standardized error messages to the user.

2.3 Key Concepts

- Product Identifier: A unique code used to pinpoint a specific item in the database.
- Validation: A security and quality check to ensure the request is formatted correctly before the system attempts to process it.
- Standardized Error Responses: Consistent messages provided by the system when a request fails (e.g., "Not Found" or "Unauthorized"), ensuring the user understands exactly why an action could not be completed.
- Resource: In this context, a "resource" refers to the specific product data being requested.

2.4 Business Value

This feature is essential for enabling seamless integration between our ERP system and other applications. By providing a reliable and standardized way to fetch individual product data, we ensure that external systems can accurately display or utilize our product catalog information. Furthermore, the built-in error handling improves the developer experience by providing clear feedback when requests fail, reducing troubleshooting time and increasing overall system reliability.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id/purchases

Prepared by Kolosal AI

Version 1.0	**Date** October 20, 2026	**Status** Draft	**Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to view the purchase history for a specific product directly on its detail page. By using this tool, users can see a list of all recorded purchases associated with a product, including details like the supplier, quantity, date, and price. The feature also includes flexible options to filter these results by supplier, sort them by specific criteria, and control how many records appear at once.

1.2 Step-by-Step Flow

1. Validation: The system first checks that the provided product ID is in the correct format.
2. Verification: The system confirms that a product with that ID actually exists in the database.
3. Authorization: The system verifies that the current user has the necessary permissions to view purchase information for that specific product.
4. Filtering & Sorting: The system processes any optional requests to filter by a specific supplier, sort the list (e.g., by date), or limit the number of results displayed.
5. Data Retrieval: The system gathers the matching purchase records and presents them to the user. If any errors occur during this process, the system provides an appropriate status message.

1.3 Key Concepts

- Product ID: A unique identifier used to ensure the system retrieves purchase history for the exact item being viewed.
- Filtering: The ability to narrow down the list of purchases to show only those from a specific supplier.
- Sorting: The ability to organize the purchase list in a preferred order, such as showing the most recent purchases first.
- Pagination: A control mechanism that limits the number of records returned at one time to ensure the page remains fast and easy to read.
- Authorization: A security check that ensures only users with the correct access rights can view sensitive purchase data.

1.4 Business Value

This feature enhances the product detail page by providing immediate transparency into supply chain and procurement history. By allowing users to quickly filter and sort purchase data, it enables faster decision-making regarding inventory management and supplier performance, all while maintaining strict data security through integrated permission checks.

2. Data

2.1 Overview

This feature provides a way to retrieve the purchase history for a specific product. It is designed to be used on a product detail page, allowing users to see a list of all purchases associated with that item. To make the data easier to navigate, the feature includes options to filter by supplier, sort the results, and limit the number of records displayed at once.

2.2 Step-by-Step Flow

1. Product Verification: The system first checks if the requested product exists in the database. If the product cannot be found, the request is stopped.
2. Query Initialization: The system prepares to search for all purchase records linked to the specific product ID provided.
3. Supplier Filtering: If a specific supplier is requested, the system narrows the search results to only include purchases from that supplier.
4. Sorting: If sorting instructions are provided (e.g., by date), the system organizes the list accordingly.
5. Pagination: If a limit on the number of records is specified, the system restricts the output to that amount.
6. Data Retrieval: The system gathers the final, filtered, and sorted list of purchases and returns them to the user.

2.3 Key Concepts

- Product ID: A unique identifier used to ensure the system retrieves purchase history for the correct item.
- Supplier Filter: An optional tool that allows users to view purchases from a specific vendor rather than the entire history.
- Sorting: The ability to arrange the purchase list in a specific order, such as showing the most recent purchases first.
- Pagination: A method to control the volume of data returned, ensuring the page remains fast and easy to read by limiting the number of records shown at one time.

2.4 Business Value

This feature enhances the product detail page by providing transparency into procurement history. By allowing users to filter and sort this data, it enables faster decision-making and easier auditing of supply chain activities. It ensures that stakeholders can quickly find relevant purchase information without having to manually sift through large volumes of data.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id/warehouse-stocks

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to check the inventory levels of a specific product across different warehouse locations. By providing a product ID, users can retrieve a detailed list showing how much stock is currently on hand at each warehouse, along with location details and the date the information was last updated. The feature also supports filtering and pagination, making it easy to find specific warehouse data even when a product is stored in many locations.

1.2 Step-by-Step Flow

1. Product Verification: The system first checks if the requested product exists in the database. If the product cannot be found, the request is stopped, and an error is returned.
2. Applying Filters: The system applies any optional filters provided by the user, such as a specific warehouse ID, warehouse name, or location code, to narrow down the search results.
3. Data Retrieval: The system gathers the relevant stock records for the product, combining them with the corresponding warehouse information.
4. Pagination: The system organizes the results into pages based on the requested limit and page number to ensure the data is easy to manage and display.
5. Final Output: The system returns a summary of the total number of records found, followed by a detailed list containing the stock quantity, warehouse name, location code, and the last update timestamp for each entry.

1.3 Key Concepts

- Product ID: A unique identifier used to specify exactly which item you want to check the stock for.
- Warehouse Filters: Optional criteria (like name or location code) that allow you to search for stock in specific warehouses rather than viewing the entire list.
- Pagination: A method of breaking large lists of data into smaller, manageable chunks (pages) to improve performance and readability.
- Stock on Hand: The actual quantity of a product currently available in a specific warehouse.
- Last Updated: A timestamp indicating the most recent time the stock information for that specific warehouse was modified.

1.4 Business Value

This feature enables inventory managers and sales staff to quickly identify where a product is stored and how much is available. By allowing users to filter by location and view real-time stock levels, the business can improve order fulfillment accuracy, prevent overselling, and optimize stock distribution across the warehouse network.

2. Data

2.1 Overview

This feature provides a simple way to check the current inventory levels for a specific product across all company warehouses. By requesting information for a particular item, the system will return a clear list showing exactly how much stock is available at each location and when that information was last updated.

2.2 Step-by-Step Flow

1. Product Verification: The system first confirms that the product you are inquiring about actually exists in the database. If the product cannot be found, the system will notify you that the request is invalid.
2. Data Retrieval: Once the product is confirmed, the system searches through the inventory records to find all entries associated with that specific item.
3. Information Consolidation: The system gathers the relevant details, matching the stock quantities with the specific names of the warehouses where they are stored.
4. Final Output: The system presents a clean list containing the warehouse name, the current quantity on hand, and the timestamp of the most recent inventory update.

2.3 Key Concepts

- Product ID: A unique identifier used to ensure the system retrieves information for the exact item you are looking for.
- Warehouse Stock: The specific count of a product currently held at a particular storage location.
- Inventory Visibility: The ability to see real-time stock levels across multiple locations, ensuring accurate reporting and planning.

2.4 Business Value

This feature improves operational efficiency by providing instant visibility into inventory distribution. Instead of manually checking multiple locations, staff can quickly identify which warehouses have sufficient stock to fulfill orders. This helps prevent stockouts, improves order fulfillment speed, and ensures that inventory data is transparent and up-to-date for better decision-making.

BUSINESS REQUIREMENTS DOCUMENT

Product Schema

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Product Schema feature provides a unified way to access and manage comprehensive product information within the ERP system. Instead of looking at fragmented data, this feature consolidates core product details—such as pricing, branding, and categorization—with real-time inventory levels across stores and warehouses. It also includes audit capabilities to track historical changes to product settings and pricing.

1.2 Step-by-Step Flow

1. Consolidated Data Retrieval: When you request product details, the system performs a single, efficient operation that joins core product information with its associated brand, type, tags, and current stock levels in both stores and warehouses.
2. Inventory Calculation: The system automatically calculates the "available" stock by taking the total inventory and subtracting items that are currently reserved or held on consignment.
3. Historical Audit: If you need to review past changes, the system retrieves a chronological log of updates for a specific product, including previous pricing, tax status, and configuration settings.
4. Warehouse-Specific Analysis: For deeper inventory management, the system can pull detailed stock reports for specific warehouses, including cost analysis and transit status, filtered by your specific needs.
5. Pagination: To ensure the system remains fast and responsive, all lists of products or history logs are returned in manageable chunks using pagination (limiting the number of items per page).

1.3 Key Concepts

- Consolidated Record: A single view that combines data from multiple sources (products, brands, types, and stock locations) so you don't have to manually piece information together.
- Available Quantity: The actual stock ready for sale, calculated by excluding reserved items and consignment stock from the total inventory.
- Audit Log: A historical record of changes made to a product, allowing you to see who changed a price or setting and when it happened.
- Pagination: A method of breaking large amounts of data into smaller, numbered pages to improve performance and readability.
- SKU (Stock Keeping Unit): The unique identifier used to track specific products across all store and warehouse locations.

1.4 Business Value

- Improved Decision Making: By having a single, accurate view of product data and real-time stock levels, managers can make faster, more informed decisions about pricing and inventory replenishment.

- Operational Efficiency: Consolidating multiple data points into one request reduces the time and effort required to generate reports or view product status.
- Enhanced Accountability: The historical audit log provides transparency, ensuring that all changes to product pricing or status are tracked and can be reviewed for accuracy.
- Better Inventory Control: With clear visibility into reserved and available stock, the business can prevent overselling and optimize stock distribution across different locations.

BUSINESS REQUIREMENTS DOCUMENT

Common Standard Response JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature introduces a standardized format for all API responses within the ERP system. By establishing a consistent structure for both successful operations and error messages, we ensure that the software communicates with other systems in a predictable, reliable way. This eliminates ambiguity for developers and external systems when interpreting the outcome of an API request.

1.2 Step-by-Step Flow

1. Request Processing: When an API request is made, the system processes the action (e.g., creating a resource or retrieving data).
2. Outcome Determination: The system identifies the result of the request, mapping it to a standard HTTP status code (such as 201 for success, or various 4xx/5xx codes for errors).
3. Response Construction: Using a centralized factory tool, the system automatically wraps the result into a predefined, consistent JSON structure.
4. Standardized Delivery: The final response is delivered to the requester, ensuring that fields like `status`, `error`, `message`, and `data` are always presented in the same format, regardless of the specific endpoint used.

1.3 Key Concepts

- Standardized Response Structure: A uniform "template" for all API communications, ensuring that every response contains the same core information in the same format.
- HTTP Status Codes: Numerical codes that act as a shorthand for the outcome of a request (e.g., "201" confirms a successful creation, while "404" indicates a missing resource).
- Response Factory: A behind-the-scenes utility that ensures developers follow the standard format every time they build a new API feature, preventing "custom" or inconsistent response styles.
- Validation Errors: Specific, structured feedback provided when a request is well-formed but contains data that the system cannot process (e.g., missing required fields).

1.4 Business Value

- Improved Reliability: By enforcing a consistent structure, we reduce the likelihood of integration errors between different parts of the ERP system.
- Faster Development: Developers no longer need to decide how to format error messages or success responses for every new feature; they can use the pre-built factory, saving time and reducing bugs.
- Easier Troubleshooting: Because error messages follow a predictable format, support teams and developers can quickly identify and resolve issues when an API call fails.

- Better System Interoperability: A standardized API makes it significantly easier for third-party applications or future modules to connect and communicate with our ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

Purchase History JSON Schema

Prepared by Kolosal AI

Version 1.0	**Date** October 20, 2026	**Status** Draft	**Classification** Internal

1. Data

1.1 Overview

The Purchase History feature establishes a standardized digital format for recording every product purchase made by the organization. This structure ensures that all purchase data—including product details, supplier information, and financial breakdowns—is captured consistently across the system. Additionally, the feature includes an automated verification step to ensure that all financial calculations (such as subtotals and final totals) are mathematically accurate before the data is saved.

1.2 Step-by-Step Flow

1. Data Entry: A purchase record is initiated, capturing essential details such as the unique purchase ID, product ID, supplier ID, delivery ID, and the date of the transaction.
2. Financial Input: The system records the quantity purchased, the unit price, and any applicable tax.
3. Automated Calculation: The system automatically calculates the subtotal (quantity multiplied by unit price) and the final total (subtotal plus tax).
4. Validation: The system performs a background check to compare the provided subtotal and total against the calculated values.
5. Confirmation: If the figures match, the record is validated and accepted; if there is a discrepancy, the record is flagged to prevent financial errors.

1.3 Key Concepts

- Schema: A standardized "blueprint" that defines exactly what information must be included in a purchase record and how it should be formatted.
- Validation: An automated quality-control process that ensures the numbers provided in a record are mathematically consistent.
- Subtotal: The cost of the items purchased before any taxes are applied.
- Total: The final amount due, representing the sum of the subtotal and the tax.

1.4 Business Value

- Data Integrity: By enforcing a strict format, we eliminate "dirty data" and ensure that every purchase record contains all necessary information for reporting and auditing.
- Error Prevention: The automated validation logic acts as a safeguard, preventing human or system entry errors from resulting in incorrect financial totals.
- Operational Efficiency: Standardizing this data allows different parts of the ERP system to communicate seamlessly, ensuring that inventory, supplier management, and accounting teams are all working from the same accurate information.

BUSINESS REQUIREMENTS DOCUMENT

Product

Prepared by Kolosal AI

Version 1.0 **Date** October 20, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Product feature serves as the central hub for managing inventory and catalog information within the ERP system. It provides a structured way to define products, categorize them by brand and type, and track their movement, pricing, and history across different locations (stores and warehouses). This system ensures that every item has a unique identifier and that all changes—whether in stock levels or pricing—are recorded for audit and operational accuracy.

1.2 Step-by-Step Flow

1. Product Definition: New products are created with unique identifiers (SKUs), names, and classifications (Brand and Type).
2. Inventory Tracking: The system monitors stock levels separately for retail stores and central warehouses, ensuring accurate availability counts.
3. Stock Movement: Any change in stock (increases or decreases) at a store is logged in a history table, capturing the reason for the change (e.g., sales or transfers).
4. Pricing Management: The system maintains a history of price changes and allows for specialized pricing (such as regional or customer-group specific rates) to be tracked against the product.
5. Operational Metadata: Products can be tagged for easier organization, and the system maintains a comprehensive purchase history to track how and when items were acquired.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique code assigned to each product to ensure it can be identified and tracked accurately across the entire system.
- Foreign Key: A logical link that connects data across tables; for example, ensuring that a "Store Stock" record is always tied to a valid "Product."
- Stock Tracking: The ability to monitor inventory levels in real-time across different locations, including reserved or consignment stock in warehouses.
- Audit History: Dedicated tables that record changes to product status, pricing, and stock levels, providing a clear trail of who changed what and when.
- Price Tracking: A flexible mechanism to manage different price tiers (e.g., wholesale vs. retail) and apply specific price overrides based on the location or customer group.

1.4 Business Value

- Operational Efficiency: By centralizing product data and automating stock updates, the system reduces manual entry errors and provides a single source of truth for inventory.

- Informed Decision Making: With detailed purchase and price history, management can analyze trends, track supplier performance, and make better-informed pricing strategies.
- Scalability: The modular design allows the business to easily add new stores, warehouses, or product categories without disrupting existing operations.
- Accountability: The audit logs for stock changes and price updates ensure transparency and security, making it easier to reconcile inventory and investigate discrepancies.
