Product List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product List Page serves as the central hub for managing your inventory within the Lumi ERP system. It provides a clear, organized view of all products, allowing users to quickly locate specific items, monitor stock levels, and manage product status. The page is designed to be highly searchable and filterable, ensuring that users can efficiently navigate large catalogs to find the information they need.

1.2 Step-by-Step Flow

1. Initial Loading: When you first open the page, the system automatically retrieves and displays a list of "Active" products.
2. Status Filtering: You can toggle between "Active" and "Inactive" product lists using the tabs provided. Switching tabs automatically refreshes the table to show only the relevant items.
3. Advanced Searching: You can narrow down the product list by entering specific criteria into the filter bar (such as SKU, Name, Product Code, Brand, or Category).
4. Applying Filters: Once your search criteria are set, clicking the "Apply Search" button triggers the system to fetch and display the filtered results.
5. Viewing Details: Each product name in the list acts as a link. Clicking on a product name will take you directly to that item's dedicated details page for further review or editing.
6. Adding New Items: A dedicated button is available to transition you to the "Add Product" page whenever you need to register a new item in the system.

1.3 Key Concepts

- Status Tabs: A quick-access control to switch between viewing currently active products and those that have been deactivated.
- Filter Bar: A collection of search fields that allow you to pinpoint products based on specific attributes like SKU, name, or brand.
- Product Table: The main display area that organizes product data into columns, including pricing, stock levels, and tax information, for easy comparison.
- Pagination: The system automatically manages large lists by breaking them into manageable pages, ensuring the interface remains fast and responsive.

1.4 Business Value

-

Operational Efficiency: By providing robust search and filter capabilities, staff can spend less time hunting for product information and more time on core tasks.

- Improved Data Accuracy: Centralizing product management with clear status indicators (Active/Inactive) helps prevent errors in inventory tracking and procurement.
- Streamlined Workflow: The direct navigation to product details and the quick-access "Add Product" feature reduce the number of clicks required to perform daily inventory management duties.

2. Logic

2.1 Overview

The Product List Page is designed to help users efficiently browse and manage the company's product catalog. It provides a centralized view where users can see key product details, search for specific items, and filter the list based on their current status (Active or Inactive). The page is built to handle large amounts of data by loading products in manageable segments.

2.2 Step-by-Step Flow

1. Initial Load: When the page first opens, it automatically displays a list of "Active" products, showing the first 20 items by default.
2. Filtering by Status: Users can toggle between "Active" and "Inactive" tabs. Selecting a tab refreshes the list to show only products matching that status.
3. Searching: Users can enter a keyword into the search bar. Upon clicking the "Apply Search" button, the system filters the product list by name or SKU to find the specific items requested.
4. Data Display: The system retrieves the relevant product information—such as the name, price, stock levels, and status—and presents it in a clear, organized table for the user.

2.3 Key Concepts

- Pagination: A method of breaking the product list into smaller, manageable pages (e.g., 20 items at a time) to ensure the page remains fast and easy to navigate.
- Status Filtering: A feature that allows users to isolate products based on their operational state, specifically distinguishing between active and inactive inventory.
- Search Criteria: The ability to look up products using either their unique identification number (SKU) or their common name.
- Data Mapping: The process of taking raw product information from our database and translating it into a user-friendly format for the screen, ensuring that details like price and stock quantity are clearly labeled.

2.4 Business Value

This feature streamlines inventory management by reducing the time spent searching for products. By providing quick access to active and inactive items, staff can maintain accurate records and respond to stock inquiries faster. The use of pagination and targeted search ensures that even as the product catalog grows, the system remains responsive and easy to use, directly supporting more efficient daily operations.

3. Data

3.1 Overview

The Product List Page feature provides a centralized hub for users to view, search, and organize the company's product catalog. It is designed to help staff quickly locate specific items by narrowing down large lists using categories, status updates, or keyword searches. The page also includes a pagination system to ensure the interface remains fast and easy to navigate, even as the product database grows.

3.2 Step-by-Step Flow

1. Category Retrieval: The system automatically loads a list of all available product categories to populate the filter dropdown menu.
2. User Input: The user enters a search term (such as a product name or SKU), selects a specific category, or chooses a product status (e.g., active or discontinued).
3. Data Filtering: The system applies these selected criteria to the product database to narrow down the results.
4. Pagination: The system divides the filtered results into manageable pages, displaying only a set number of products at a time based on the user's current view.
5. Display: The system presents the filtered list of products to the user, along with a total count of items found, allowing the user to navigate through the pages.

3.3 Key Concepts

- Search Query: A text-based search that looks for matches within product names or unique identification codes (SKUs).
- Category Filtering: A way to group products by their specific type or department to reduce clutter.
- Status Filtering: A method to view products based on their current operational state, such as whether they are currently available for sale.
- Pagination: A navigation tool that breaks a large list of items into smaller, numbered pages to improve page loading speed and readability.
-

Metadata: Information provided by the system—such as the total number of items found—that helps the user understand the scope of their search results.

3.4 Business Value

This feature significantly improves operational efficiency by reducing the time staff spend searching for product information. By providing robust filtering and organized navigation, the system ensures that users can access accurate, real-time product data without being overwhelmed by the total volume of the catalog. This leads to faster decision-making and more accurate inventory management.

BUSINESS REQUIREMENTS DOCUMENT

Product Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Details feature provides a comprehensive, read-only view of a specific product within the Lumi ERP system. It is designed to help users quickly access all relevant information about an item—such as pricing, stock levels, warranty, and tax details—without needing to navigate through multiple screens. The page is optimized for usability, featuring sticky headers that keep essential product identification and navigation tools visible at all times while scrolling through detailed information.

1.2 Step-by-Step Flow

1. Page Initialization: When a user selects a product, the system automatically loads the full set of product data using the unique product identifier.
2. Sticky Navigation: The top of the screen displays a persistent navigation bar and an "Identity Bar" (showing the SKU and Name), which remain fixed as the user scrolls.
3. Core Details: The page displays the primary product information, including the description, current price, stock quantity, and category.
4. Quick Actions: Users can trigger specific tasks directly from the page, such as navigating back to the product list, editing the product, or generating QR codes and barcodes.
5. Detailed Information Cards: The remainder of the page is organized into a grid of specialized "cards." Each card provides focused, read-only data on specific aspects of the product, such as:

* Operational Data: Attributes, tracking/bundle status, and settings.

* Financial & Legal: Tax, company/store pricing, external pricing (MRP), and trade-in values.

* Logistics & Support: Warranty periods, return policies, dimensions, and product schedules.

* Audit Trail: A history of changes made to the product record.

1.3 Key Concepts

- Identity Bar: A fixed header element that displays the product's SKU and Name, ensuring the user always knows which item they are viewing.
- Read-Only Cards: Organized sections of the page that present specific data points (like warranty or tax info) in a clean, structured format without allowing direct editing on this specific view.
- Sticky Positioning: A design choice that keeps the navigation and product identity visible at the top of the screen, even when the user scrolls down to view long lists of information.
-

Product Identifier: The unique code used by the system to fetch the correct, up-to-date information for the specific item being viewed.

1.4 Business Value

- Efficiency: By consolidating all product-related data into a single, well-organized view, users save time that would otherwise be spent searching through different modules or reports.
- Accuracy: Providing a clear, read-only view of critical data (like pricing, tax, and warranty) reduces the risk of errors during customer interactions or inventory management.
- Improved Workflow: The inclusion of direct links to edit the product or generate labels (QR/Barcode) streamlines the transition between viewing information and taking action, keeping the user's workflow uninterrupted.

2. Logic

2.1 Overview

The Product Details feature provides a comprehensive, read-only view of a specific item within the Lumi ERP system. When a user selects a product, the system retrieves all relevant information—such as identification, pricing, stock status, and category details—and organizes them into a structured, two-column layout for easy reference.

2.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the Product Details page, the system automatically triggers a request to fetch the specific data for that product.
2. Data Retrieval: The system pulls the raw product information from the database, including core identifiers, pricing, and stock levels.
3. Information Mapping: The system maps the retrieved data to the specific labels and fields required by the user interface.
4. Layout Organization: The information is displayed in a two-column format:

* Left Column: Focuses on core details, tax information, pricing structures, and stock/bundle tracking.

* Right Column: Focuses on administrative data, product attributes, physical dimensions, scheduling, and specific business settings like warranty and return policies.

2.3 Key Concepts

- Product Entity: The central record containing all information about an item, such as its name, SKU, and pricing.
-

Read-Only View: A display mode where information is presented for viewing purposes only, ensuring data integrity by preventing accidental changes while browsing.

- Two-Column Layout: A structured design approach that groups related information (e.g., pricing vs. dimensions) to help users find specific details quickly.
- Stock Tracking: A status indicator that confirms whether the system is actively monitoring the inventory levels for that specific product.

2.4 Business Value

This feature serves as the "single source of truth" for product information within the ERP. By centralizing complex data—ranging from supply costs and tax codes to warranty periods and physical dimensions—it enables staff to make informed decisions regarding procurement, sales, and inventory management without needing to cross-reference multiple documents or systems.

3. Data

3.1 Overview

The Product Details feature allows users to view comprehensive information about a specific item within the Lumi ERP system. When a user selects a product, the system retrieves all relevant data—such as pricing, stock levels, and descriptive information—and presents it in a clear, organized format for easy review.

3.2 Step-by-Step Flow

1. Request Initiation: When a user navigates to a specific product page, the system triggers a request to retrieve that item's unique information.
2. Data Retrieval: The system searches the database for the product and automatically pulls in its associated category name to provide full context.
3. Data Formatting: The raw information is gathered and organized into a standardized structure, ensuring that details like the description, price, and inventory count are grouped logically.
4. Display: The formatted information is delivered to the screen, providing the user with a complete view of the product's attributes.

3.3 Key Concepts

- Product Record: The central collection of data for an item, including its unique identifier, name, and physical description.
- Category Association: Linking a product to a specific group (e.g., "Electronics" or "Office Supplies") to help users better understand how the item is classified.

- Inventory Count: The current number of units available in stock, providing real-time visibility into product availability.
- Standardized Mapping: The process of taking raw system data and translating it into a clean, user-friendly format for the interface.

3.4 Business Value

This feature provides a "single source of truth" for product information, reducing the time staff spend searching for details across different systems. By consolidating pricing, stock levels, and categorization into one view, the system enables faster decision-making, more accurate inventory management, and a more efficient workflow for team members handling product data.

BUSINESS REQUIREMENTS DOCUMENT

Add Product

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Product" feature provides a comprehensive form within the Lumi ERP system that allows users to register new products into the database. This interface captures all necessary details—ranging from basic identification and pricing to advanced logistics and inventory settings—ensuring that every new item is fully defined for use across the system.

1.2 Step-by-Step Flow

1. Access the Form: The user navigates to the product section of the application, where the "Add Product" form is presented.
2. Input Product Details: The user fills in the required and optional fields, which are categorized into:

* Basic Information: SKU, Name, Description, Type, Brand, and Tags.

* Pricing & Tax: Retail, Wholesale, and Supply prices, along with tax settings and Maximum Retail Price (MRP).

* Logistics & Inventory: Weight, Volume, Stock Tracking, and Bundle settings.

* Operational Settings: Barcode types, Warranty periods, Return limits, and status toggles (e.g., Active, Internal Product, Can Order).

* Media & Attributes: Uploading product images and defining specific product attributes.

3. Submit Data: Once the form is complete, the user clicks the "Save" button. The system validates the entries and sends the information to the database to create the new product record.
4. Cancel Action: If the user decides not to proceed, they can click the "Cancel" button at any time to discard their changes and return to the product list page.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track individual products within the system.
- Pricing Tiers: Different price points (Retail, Wholesale, Supply) that allow the system to handle various sales scenarios and tax calculations.
- Product Attributes: Customizable fields that allow for specific descriptive data to be attached to a product.
- Bundle: A feature that allows multiple items to be grouped and sold together as a single product unit.
- Stock Tracking: A setting that determines whether the system should monitor the inventory levels for that specific item.
-

Quick Button: A configuration for Point of Sale (POS) systems that allows a product to be displayed as a shortcut button for faster checkout.

1.4 Business Value

This feature centralizes product management, ensuring that all relevant data—from financial pricing to physical dimensions—is captured in one place. By providing a structured and detailed input process, the system reduces data entry errors and ensures that downstream processes, such as inventory tracking, sales reporting, and tax calculations, are accurate and consistent across the entire organization.

2. Logic

2.1 Overview

The "Add Product" feature allows users to register new items into the Lumi ERP system. By filling out a comprehensive digital form, users can capture all necessary details—such as pricing, tax information, physical dimensions, and inventory settings—to ensure the product is correctly categorized and ready for business operations.

2.2 Step-by-Step Flow

1. Data Entry: The user completes the product form, entering details like the product name, SKU, supplier information, pricing, and physical attributes (weight/volume).
2. Image and Attribute Organization: The system automatically groups uploaded images and custom product attributes into organized sets, ensuring they are correctly linked to the new item.
3. Payload Construction: When the user clicks "Save," the system gathers all the entered information and formats it into a structured digital package.
4. Submission: The system sends this package to the central database to officially create the new product record.
5. Confirmation: The system processes the request and confirms that the product has been successfully added to the inventory.

2.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track individual products within the inventory.
- Pricing & Tax Logic: Dedicated fields for wholesale and retail pricing, including settings to specify whether these prices already include tax.
- Product Attributes: Flexible fields that allow for specific product characteristics (e.g., color, size, or material) to be attached to an item.
-

Inventory Controls: Settings that determine how a product is managed, such as whether the system should track stock levels, if the product is part of a bundle, or if it is currently active for sale.

– Operational Metadata: Information such as warranty periods, return limits, and validity dates that define the lifecycle and service terms of the product.

2.4 Business Value

This feature provides a centralized and standardized way to manage product data, reducing manual entry errors and ensuring consistency across the organization. By capturing detailed pricing, tax, and inventory information upfront, the business can maintain accurate stock levels, streamline the sales process, and ensure that financial reporting remains precise.

3. Data

3.1 Overview

The "Add Product" feature allows users to create and store comprehensive product records within the Lumi ERP system. This functionality captures all necessary details—ranging from basic identification and pricing to logistics, tax settings, and visual assets—ensuring that every product is fully defined for inventory, sales, and reporting purposes.

3.2 Step-by-Step Flow

1. Data Entry: The user inputs product information into the system, including core details (name, SKU, brand), pricing structures (wholesale, retail, MRP), and tax configurations.
2. Asset & Attribute Mapping: The system collects supplementary data, such as product images, custom attributes, physical dimensions (weight/volume), and warranty or return policy limits.
3. System Processing: The application assigns a unique identifier to the new product and organizes the provided information into the database structure.
4. Record Creation: The system saves the product record with a timestamp, enabling features like stock tracking, bundle management, and quick-access button configurations.
5. Confirmation: Once saved, the system retrieves the newly created record to confirm that the product has been successfully added to the inventory.

3.3 Key Concepts

– SKU (Stock Keeping Unit): A unique identifier used to track individual products within the inventory.

– Pricing Tiers: The system supports multiple price points, including supply, wholesale, and retail prices, with options to specify if these prices include tax.

- Product Attributes: Flexible fields that allow for custom descriptions or specifications (e.g., color, size, or material) to be attached to a product.
- Logistics & Compliance: Settings that manage physical properties (weight/volume), warranty periods, and return limits to support supply chain operations.
- Operational Flags: Settings that control how a product behaves in the system, such as whether it is active, available for ordering, or eligible for stock tracking.

3.4 Business Value

This feature provides a centralized, standardized way to manage the product catalog. By capturing granular data—such as tax codes, supplier details, and bundle configurations—the system ensures accurate financial reporting and streamlined inventory management. This reduces manual errors, improves the speed of order processing, and provides the flexibility needed to handle diverse product types within the ERP.

BUSINESS REQUIREMENTS DOCUMENT

Vouchers - Flexible Voucher Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Flexible Voucher page provides a centralized view for managing "flexible" vouchers within the Lumi ERP system. This page allows users to view a comprehensive list of existing flexible vouchers, search for specific items using filters, and navigate to a dedicated form to create new vouchers. The interface is designed to ensure that only authorized users can access the data, maintaining security across the product management workflow.

1.2 Step-by-Step Flow

1. Authentication Check: Upon loading the page, the system verifies the user's session. If the user is not logged in, they are automatically redirected to the login screen.
2. Data Retrieval: Once authenticated, the system automatically fetches all flexible vouchers to display in the table.
3. Filtering: Users can narrow down the list by entering a specific SKU or Name into the filter bar. Clicking the search button updates the table to show only the matching results.
4. Viewing Details: The table displays key information for each voucher, including pricing, validity dates, and location scopes. Users can click on a voucher's SKU to navigate to its specific details page.
5. Creating New Vouchers: Users can initiate the creation of a new flexible voucher by clicking the dedicated "New Voucher" button, which directs them to the creation form.

1.3 Key Concepts

- Flexible Voucher: A specific category of voucher where parameters (such as price) may be determined at the point of sale rather than being fixed.
- Filter Bar: A search tool that allows users to refine the voucher list by SKU or Name, ensuring they only see relevant records.
- Status Badge: A visual indicator on each row that shows the current state of the voucher (e.g., Active or Expired).
- Open Price: A feature indicating that the voucher's monetary value is not fixed and can be set during the transaction.
- Location Scope: Information defining which stores or branches are authorized to sell, issue, or redeem a specific voucher.

1.4 Business Value

-

Operational Efficiency: By providing a dedicated view for flexible vouchers, staff can quickly locate and manage specific voucher types without sifting through unrelated product data.

- Improved Accuracy: The clear display of validity dates, location scopes, and status badges reduces the risk of errors during the issuance or redemption process.
- Streamlined Workflow: The integration of search filters and direct navigation to voucher details and creation forms minimizes the time spent navigating the system, allowing for faster administrative tasks.

2. Logic

2.1 Overview

The Flexible Voucher page provides a centralized view for managing and searching flexible vouchers within the Lumi ERP system. This feature ensures that only authorized users can access the list, allows for quick filtering by specific criteria, and presents voucher details in a clear, organized table format.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies the user's session. If the user is not logged in, they are automatically redirected to the login page.
2. Data Retrieval: Once authenticated, the system automatically fetches all available "flexible" type vouchers.
3. Filtering: Users can refine the list by entering a specific SKU or Voucher Name and clicking the search button. The system then updates the table to show only the matching results.
4. Data Mapping: The system takes the raw voucher information and translates it into a user-friendly table format, ensuring that key details like pricing, validity dates, and location scopes are correctly displayed.
5. Display: The final list is rendered in the Vouchers Table, providing a clear overview of each voucher's status and usage rules.

2.3 Key Concepts

- Flexible Voucher: A specific category of voucher managed within the ERP that allows for variable pricing or usage terms.
- SKU (Stock Keeping Unit): A unique identifier used to track specific voucher products.
- Location Scope: Internal settings that define where a voucher can be sold or redeemed; while these influence the voucher's behavior, they are managed behind the scenes.
- Authentication: The security process that ensures only verified users can view or search the voucher list.

2.4 Business Value

-

Operational Efficiency: By providing a dedicated page for flexible vouchers, staff can quickly locate and verify voucher details without searching through general product lists.

- Improved Accuracy: Standardized mapping rules ensure that voucher data—such as validity periods and member-only status—is presented consistently, reducing the risk of misinterpretation.
- Enhanced Security: The integrated authentication check ensures that sensitive voucher information is protected and only accessible to authorized personnel.
- Better Decision Making: Real-time search capabilities allow users to instantly filter vouchers by name or SKU, facilitating faster responses to customer inquiries or inventory audits.

3. Data

3.1 Overview

The Flexible Voucher Page is a dedicated management view within the Lumi ERP system designed to help users easily find and monitor "flexible" type vouchers. This feature provides a clear, organized table that displays essential voucher details—such as pricing, validity dates, and redemption locations—allowing staff to manage voucher inventory efficiently.

3.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the page, the system verifies their login status. If authenticated, it automatically requests the list of all flexible vouchers.
2. Data Retrieval: The system fetches the voucher data from the database, ensuring only records categorized as "flexible" are retrieved.
3. Filtering: Users can refine the list by entering a specific SKU or voucher name into the search fields. Clicking the search button triggers a request to update the table with the filtered results.
4. Data Mapping: The system processes the raw voucher data, converting technical values (like "true/false" for member-only status) into user-friendly labels (like "Yes/No").
5. Display: The Vouchers Table Component populates with the processed data, showing key information such as price, validity periods, and status for each voucher.

3.3 Key Concepts

- Flexible Voucher: A specific category of voucher within the system that allows for variable pricing or redemption rules.
- SKU (Stock Keeping Unit): A unique identifier used to track specific voucher products in the inventory.
- Open Price: A setting that indicates whether the voucher price is fixed or can be set at the time of sale.

- Location Scope: Internal data that defines where a voucher can be sold or redeemed; while this drives system logic, it is kept behind the scenes to keep the user interface clean.
- Member Only: A status flag indicating if the voucher is restricted to registered members only.

3.4 Business Value

- Operational Efficiency: By providing a centralized, searchable list, staff can quickly locate specific vouchers without manually sorting through unrelated data.
- Improved Accuracy: Standardizing how voucher information is displayed (e.g., converting technical flags to "Yes/No") reduces the risk of misinterpretation by staff.
- Better Inventory Oversight: The clear display of validity dates and status allows managers to proactively monitor voucher lifecycles and ensure that active promotions are correctly configured.

BUSINESS REQUIREMENTS DOCUMENT

QR Code Print

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The QR Code Print feature allows users to easily generate and print custom QR code labels for products directly within the Lumi ERP system. Users can specify exactly how many labels they need and adjust the size of the codes to fit their specific packaging or inventory requirements. The system includes a preview function to ensure the labels look correct before sending them to the printer.

1.2 Step-by-Step Flow

1. Input Configuration: The user enters the desired quantity of QR codes (between 1 and 100) and the preferred size (between 50 and 500 pixels).
2. Validation: The system automatically checks that the entered values fall within the allowed ranges.
3. Preview Generation: The user clicks the "Preview" button, which generates a visual representation of the QR code based on the selected settings.
4. Review: The user views the generated preview in the on-screen card to confirm the layout and size.
5. Printing: Once satisfied with the preview, the user clicks the "Print" button to send the labels to their printer.
6. Navigation: At any point, the user can click the "Back" button to return to the previous screen without saving or printing.

1.3 Key Concepts

- Quantity Control: A setting that limits the number of labels generated in a single batch to ensure system performance and prevent errors.
- Size Customization: A setting that allows users to adjust the dimensions of the QR code to ensure it is readable and fits the physical space available on a product.
- Preview Mode: A safety feature that displays the final output on screen, allowing the user to verify settings before committing to a physical print.
- Validation: An automated check that prevents the system from processing invalid requests, such as printing zero labels or using sizes that are too small or too large to be functional.

1.4 Business Value

This feature streamlines inventory management by providing a self-service tool for labeling products. By allowing users to customize the quantity and size of QR codes on demand, the business reduces the need for external labeling services and minimizes waste. The built-in preview functionality reduces printing errors, saving both time and physical label supplies.

BUSINESS REQUIREMENTS DOCUMENT

Barcode print

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Barcode Print feature allows users to quickly generate and print physical barcode labels for products directly from the Lumi ERP system. This tool streamlines inventory management by ensuring that products can be easily identified and scanned in the warehouse or at the point of sale.

1.2 Step-by-Step Flow

1. Product Selection: The user selects the specific product they need to label from a list within the system.
2. Quantity Specification: The user enters the number of labels they wish to print for the selected product.
3. Validation: The system checks that a valid product has been chosen and that the requested quantity is at least one.
4. Generation Request: Upon clicking the print button, the system sends a request to generate the barcode labels based on the selected product and quantity.
5. Processing and Feedback: The system processes the request and provides immediate feedback if the generation is successful or if an error occurs.

1.3 Key Concepts

- Barcode Generation: The automated creation of a scannable label associated with a specific product record in the ERP.
- Label Quantity: The user-defined count of how many individual barcode stickers are required for a specific item.
- Validation: A built-in safety check that ensures the user has provided all necessary information before attempting to print, preventing errors.

1.4 Business Value

- Operational Efficiency: Reduces the time spent manually creating or sourcing labels for inventory items.
- Accuracy: Minimizes human error by pulling product information directly from the system database, ensuring the barcode matches the product record.
- Improved Inventory Control: Facilitates faster and more reliable stock tracking, cycle counting, and sales processing by ensuring every product is properly labeled for scanning.

BUSINESS REQUIREMENTS DOCUMENT

Product Edit Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Edit Page allows users to update the details of an existing product within the Lumi ERP system. When a user navigates to this page, the system automatically retrieves the current product information and populates a comprehensive form. Users can modify various attributes—such as pricing, tax settings, stock tracking, and categorization—and save their changes directly. The page also includes convenient "quick-add" features for brands and tags, allowing users to create new entries without leaving the edit screen.

1.2 Step-by-Step Flow

1. Page Load: The system fetches the existing product data using the product's unique identifier and pre-fills all form fields with the current information.
2. Data Modification: The user updates the desired fields. This includes:

* Core Details: SKU, Name, Description, Type, Brand, and Tags.

* Pricing & Tax: Supply prices, wholesale/retail pricing, tax settings, and Maximum Retail Price (MRP).

* Operational Settings: Toggles for active status, internal product status, open pricing, ordering permissions, product freezing, and stock tracking.

* Logistics & Metadata: Warranty periods, return limits, physical dimensions (weight/volume), validity dates, and custom attributes.

3. Inline Creation: If a required brand or tag is missing, the user can click the "New Brand" or "New Tag" buttons to open a quick-add overlay, create the new item, and immediately select it in the form.
4. Saving Changes: Once the user is satisfied with the updates, they click the "Save" button. The system sends the updated information to the server to finalize the changes.
5. Navigation: After saving, the system automatically redirects the user back to the product list or details page. If the user decides not to proceed, they can click "Cancel" to discard all changes and return to the previous screen.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track individual products in the inventory.
- MRP (Maximum Retail Price): The highest price at which a product can be sold to consumers.
- Inline Quick-Add: A feature that allows users to create new supporting data (like a new brand or tag) in a pop-up window without navigating away from the current page.
-

Bundle Settings: Configuration options for grouping products; note that these are locked if a product has already been sold to ensure data integrity.

– Tax/UOM (Unit of Measure): Settings that define how a product is taxed and how its quantity is measured (e.g., kilograms or liters).

1.4 Business Value

This feature provides a centralized, efficient way to maintain accurate product data. By allowing users to edit all relevant product attributes in one place—including pricing, tax, and operational flags—the system reduces administrative overhead and minimizes the risk of errors. The inclusion of inline "quick-add" buttons for brands and tags further streamlines the workflow, ensuring that users can manage their product catalog without unnecessary interruptions or navigation steps.

2. Logic

2.1 Overview

The Product Edit page allows authorized users to modify existing product information within the Lumi ERP system. When a user navigates to the edit page for a specific product, the system automatically retrieves the current details and populates a form. Once the user makes their desired changes and clicks "Save," the system updates the product record with the new information.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies the user's identity. If the user is not logged in, they are automatically redirected to the login page.
2. Data Retrieval: The system identifies the specific product from the page address and fetches its current details (such as pricing, stock settings, and descriptions) from the database.
3. Form Population: The retrieved product data is automatically mapped into the corresponding fields on the screen, allowing the user to see the current values immediately.
4. User Modification: The user updates the necessary fields in the form.
5. Submission: Upon clicking the "Save" button, the system collects all the current form values, maps them back to the product record format, and sends an update request to the server.
6. Confirmation: The system processes the update and displays a success notification if the changes were saved correctly, or an error message if the update could not be completed.

2.3 Key Concepts

– Authentication: A security check that ensures only logged-in users can access or modify product data.

- Data Mapping: The process of matching specific pieces of information (like "SKU" or "Wholesale Price") between the database and the visual form fields to ensure data is displayed and saved in the correct location.
- Payload: The collection of all product information fields that are sent to the server when the user saves their changes.
- 404 Not Found: A standard system response indicating that the requested product does not exist in the database.

2.4 Business Value

This feature provides a reliable and efficient way for staff to maintain accurate product catalogs. By automating the pre-filling of forms and providing clear feedback upon saving, the system reduces manual data entry errors and ensures that pricing, stock tracking, and product attributes remain up-to-date across the business.

3. Data

3.1 Overview

The Product Edit Page feature allows users to manage and update existing product information within the Lumi ERP system. This feature ensures that all product details—ranging from basic identification and pricing to logistics and inventory settings—can be accurately maintained and synchronized with the central database.

3.2 Step-by-Step Flow

1. Page Loading: When a user opens the edit page for a specific product, the system retrieves the current data from the database and automatically populates the form fields with the existing information.
2. Data Modification: The user updates the necessary fields in the form. This includes general details (name, description, brand), financial settings (pricing, tax, trade-in values), and operational settings (stock tracking, warranty, bundle status, and POS quick-button configurations).
3. Saving Changes: Once the user clicks the "Save" button, the system maps the updated form information into a structured format.
4. Database Update: The system performs an atomic update, ensuring all modified fields are saved to the database simultaneously to maintain data integrity.

3.3 Key Concepts

- Atomic Update: A process that ensures all changes to a product record are saved as a single, complete operation, preventing partial or inconsistent data updates.
- Product Metadata: The comprehensive set of attributes defining a product, including its identity (SKU, name), financial rules (tax, pricing, MRP), and operational constraints (stock tracking, warranty, and bundle flexibility).

- Form Mapping: The bridge between the user interface and the database, ensuring that every field visible to the user is correctly linked to the corresponding data point in the system.
- POS Quick-Button Configuration: Settings that allow specific products to be prioritized or organized for faster access at the Point of Sale.

3.4 Business Value

- Operational Accuracy: By providing a centralized and structured way to edit product details, the system reduces the risk of manual entry errors in pricing, tax, or inventory settings.
- Efficiency: The pre-filled form functionality saves time for staff by allowing them to quickly identify and update only the specific information that has changed.
- Flexibility: The inclusion of diverse attributes—such as bundle settings, warranty periods, and business unit categorization—enables the business to adapt to complex inventory needs and evolving market requirements without needing custom software changes.

BUSINESS REQUIREMENTS DOCUMENT

Service Product List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Product List Page is a centralized dashboard within the Lumi ERP system designed to help users manage their service-based offerings. This page provides a clear, organized view of all services, allowing users to quickly search, filter by status (Active or Inactive), and navigate to specific service details or create new entries.

1.2 Step-by-Step Flow

1. Page Initialization: When the page loads, the system automatically retrieves the list of active service products and displays them in a structured table.
2. Navigation: Users can orient themselves using the main menu (set to "Products") and the sub-menu (set to "Product").
3. Filtering: Users can toggle between "Active" and "Inactive" tabs to view different subsets of services.
4. Searching: A search bar allows users to type keywords to instantly narrow down the list of services displayed in the table.
5. Viewing Details: Users can click on the blue SKU or Name of any service in the table to be redirected to that specific service's detail page.
6. Adding New Services: A dedicated button at the top right allows users to navigate to a form to create a new service product.
7. Pagination: If the list of services is long, users can use the pagination controls at the bottom to browse through multiple pages of results.

1.3 Key Concepts

- Service Product: A specific type of offering in the ERP system that represents a service rather than a physical good.
- Status Filter: A toggle mechanism that allows users to view only currently "Active" services or review previously "Inactive" ones.
- Search Filter: A real-time search tool that updates the table results as the user types, making it easier to find specific items.
- Pagination: A navigation feature that breaks large lists into smaller, manageable pages to improve performance and readability.
- SKU: A unique identifier for each service product, used here as a primary link to access detailed information.

1.4 Business Value

This feature streamlines the management of service offerings by providing a single, efficient interface. By enabling quick searching and status-based filtering, staff can spend less time looking for information and more time managing their service catalog. The ability to easily jump to detailed records or create new services ensures that the product database remains accurate and up-to-date, directly supporting smooth operational workflows.

2. Logic

2.1 Overview

The Service Product List Page is a centralized hub within the Lumi ERP system designed to help users efficiently manage and browse service-based offerings. This feature provides a clear, organized view of all services, allowing users to quickly locate specific items using search tools and status-based filtering.

2.2 Step-by-Step Flow

1. Initial Load: When the page opens, the system automatically retrieves all "Active" service products to display in the main table.
2. Status Filtering: Users can toggle between "Active" and "Inactive" tabs. Selecting a tab updates the list to show only the services relevant to that lifecycle state.
3. Keyword Search: Users can enter text into the search bar to find specific services. The system scans the service name, unique identification code (SKU), and description to return matching results.
4. Data Presentation: The system compiles the relevant service details—including the service type, category tag, estimated duration, and pricing—and presents them in a clean, readable table format for the user.

2.3 Key Concepts

- Service Product: A non-physical offering (such as a consultation or maintenance task) managed within the ERP system.
- Status Filter: A toggle mechanism that separates services based on their current operational state (Active vs. Inactive), helping to reduce clutter.
- Search Logic: A flexible search tool that looks across multiple fields (name, SKU, and description) simultaneously to ensure users find what they need regardless of how they search.
- Service Details: The specific attributes displayed for each item, such as the time required to perform the service and the price before tax.

2.4 Business Value

This feature streamlines administrative workflows by providing a single source of truth for all service offerings. By enabling quick searching and status-based filtering, staff can spend less time hunting for information and more

time managing service delivery. This improves operational efficiency and ensures that pricing and service duration data remain easily accessible for accurate quoting and scheduling.

3. Data

3.1 Overview

The Service Product List Page is a centralized dashboard within the Lumi ERP system designed to help users efficiently browse, manage, and view details for all service-based offerings. This feature provides a structured table view that displays key information—such as pricing, tax details, and service duration—for every service product in the system.

3.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the Service Product List page, the system automatically requests the first set of service products from the database.
2. Data Retrieval: The system fetches the list of services, organizing them alphabetically by name to ensure a consistent and predictable layout.
3. Pagination Handling: To keep the page performant and easy to read, the system displays a specific number of items at a time. Users can navigate through the full list using pagination controls (such as "Next," "Previous," and specific page numbers).
4. Data Display: The retrieved information is mapped into a clean, readable table format, showing details like the SKU, service name, description, pricing, and tax configurations.
5. User Interaction: As the user clicks through different pages, the system repeats the retrieval process to load the next set of records dynamically.

3.3 Key Concepts

- Service Product: A specific type of offering in the ERP system that represents a service rather than a physical good, characterized by attributes like estimated time and specific tax accounts.
- Pagination: A method of dividing a large list of items into smaller, manageable pages to improve loading speed and user experience.
- SKU (Stock Keeping Unit): A unique identifier assigned to each service product to ensure accurate tracking and reporting.
- Open Price: A setting that indicates whether a service allows for flexible or variable pricing at the time of sale.
- Tax Configuration: Specific fields identifying which tax rules and accounting codes apply to a particular service.

3.4 Business Value

This feature streamlines administrative tasks by providing a single source of truth for all service offerings. By organizing services into a searchable, paginated list, staff can quickly verify pricing, tax settings, and service durations without needing to open individual records. This improves operational efficiency, reduces manual lookup time, and ensures that service-related data remains consistent across the organization.

Vouchers - New Flexible Voucher Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Flexible Voucher" page is a dedicated interface within the Lumi ERP system that allows staff to create and configure new flexible voucher products. This page provides a structured form to define the voucher's identity, validity rules, and usage locations, ensuring that all necessary business data is captured before the voucher is made available in the system.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically fetches necessary configuration data (such as available product conditions and external publisher options) to populate the dropdown menus.
2. Data Entry: The user fills out the form, providing essential details such as the unique SKU, the voucher name, and an optional description.
3. Configuration: The user defines the voucher's behavior, including:

* Setting the validity period (in days or months) and specific start/end dates.

* Selecting where the voucher can be sold, issued, or redeemed.

* Assigning the voucher to specific members or keeping it open to all customers.

* Choosing a product condition (e.g., by product list or by type/brand).

4. Validation: Upon clicking "Save," the system checks that the mandatory fields (SKU and Name) have been completed.
5. Submission: If valid, the system saves the new flexible voucher to the database.
6. Completion: The user is redirected to the main voucher list page. If the user decides not to proceed, they can click "Cancel" to discard all changes and return to the list page.

1.3 Key Concepts

- SKU: A unique identifier used to track and manage the voucher product within the ERP system.
- Flexible Voucher: A versatile voucher type that allows for customizable pricing, validity, and redemption rules.
- Open Price: A setting that, when enabled, allows the voucher price to be flexible rather than fixed.
- Product Condition: A rule set that determines which specific products or categories the voucher applies to.
- Redemption/Issue Locations: Specific store locations authorized to sell or accept the voucher.
- External Publisher: A third-party entity or partner associated with the issuance or promotion of the voucher.

1.4 Business Value

This feature streamlines the product management process by providing a centralized, user-friendly way to create flexible vouchers. By enforcing mandatory fields and providing clear configuration options for validity and location, the system reduces manual entry errors and ensures that all vouchers are correctly categorized and restricted according to business policy. This ultimately improves operational efficiency and provides better control over promotional and financial voucher programs.

2. Logic

2.1 Overview

The "New Flexible Voucher" feature allows administrators to create and configure new voucher products within the Lumi ERP system. This page provides a structured way to define voucher details—such as pricing, validity periods, and usage locations—ensuring that all necessary information is captured accurately before the voucher is made available for use.

2.2 Step-by-Step Flow

1. Data Entry: The user fills out the voucher form, providing details such as the unique SKU, name, description, pricing rules, and validity dates.
2. Validation: Upon clicking "Save," the system automatically checks the input for errors. It ensures the SKU is unique, prevents conflicting expiration settings (e.g., setting both months and days), and confirms that a price is provided if the voucher does not have an "open price."
3. Mapping: If the data is valid, the system organizes the form information into the required format for the database.
4. Persistence: The system saves the new voucher record to the database.
5. Confirmation: Once successfully saved, the system returns a confirmation containing the new voucher's unique ID, SKU, and creation timestamp.

2.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier for the voucher product, used to distinguish it from other items in the system.
- Open Price: A setting that allows the voucher price to be determined at the time of sale rather than being fixed in advance.
- Validation Rules: Automated checks that prevent the creation of vouchers with missing or logically conflicting information.
-

Flexible Expiration: The ability to define how long a voucher remains valid, either by a specific date range or a duration (months/days).

- Location Mapping: The ability to specify exactly where a voucher can be sold/issued and where it can be redeemed.

2.4 Business Value

This feature streamlines the product management process by providing a standardized, error-proof method for creating vouchers. By enforcing data consistency at the point of entry, the system reduces administrative errors and ensures that vouchers are correctly configured for sales and redemption, ultimately supporting more reliable financial tracking and customer experience.

3. Data

3.1 Overview

The new Flexible Voucher feature allows your team to create and manage versatile voucher products within the Lumi ERP system. This feature is designed to be highly configurable, enabling you to define specific pricing, validity periods, and location-based rules for each voucher. By centralizing this process, the system ensures that every voucher is uniquely identified and correctly tracked from the moment it is created.

3.2 Step-by-Step Flow

1. Data Entry: You input the voucher details into the system, including its unique identifier (SKU), name, pricing structure, and validity rules.
2. Validation: The system automatically checks that the SKU is unique to prevent duplicate records. If a duplicate is found, the system will alert you to correct it.
3. Configuration: The system captures specific business rules, such as whether the price is fixed or open, where the voucher can be sold or redeemed, and any specific membership requirements.
4. Persistence: Once validated, the system saves the voucher details into the database, assigning it a unique internal ID and a timestamp for audit purposes.
5. Confirmation: Upon successful creation, the system confirms that the voucher is active and ready for use.

3.3 Key Concepts

- SKU (Stock Keeping Unit): A unique code used to identify a specific product, ensuring no two vouchers are confused in the system.
- Open Price: A setting that allows the voucher price to be flexible or determined at the time of sale, rather than being fixed.

- Validity Rules: Configurable timeframes (days or months) or specific calendar dates that dictate when a voucher can be used.
- Location Mapping: The ability to define specific branches or locations where a voucher can be issued (sold) and where it can be redeemed.
- External Publisher: A field to track if the voucher is being managed or issued by a third-party partner.

3.4 Business Value

- Operational Efficiency: By automating the creation and validation process, staff can quickly launch new promotional vouchers without manual oversight.
- Flexibility: The ability to set custom redemption locations and variable pricing allows the business to run targeted marketing campaigns tailored to specific regions or customer segments.
- Data Integrity: Automated SKU validation prevents errors in inventory and financial reporting, ensuring that every voucher sold is accurately accounted for in the ERP.
- Scalability: The structured approach to defining voucher rules makes it easy to manage a large catalog of diverse products as the business grows.

BUSINESS REQUIREMENTS DOCUMENT

Vouchers - Detail Flexible Voucher Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Detail Flexible Voucher" page provides a centralized view for staff to review the specific configuration of a flexible voucher product. This page acts as a read-only dashboard that pulls data from the system to display everything from pricing and validity periods to redemption locations and administrative audit logs. It ensures that staff have a clear, consistent understanding of how a voucher is structured before it is issued to a customer.

1.2 Step-by-Step Flow

1. Navigation: The user accesses the page via the main menu (under the Products module) and the secondary product sub-menu.
2. Data Retrieval: Upon loading, the system automatically fetches the specific voucher record from the database using its unique identifier.
3. Loading State: While the data is being retrieved, the user sees a loading indicator to confirm the system is processing the request.
4. Display: Once the data is retrieved, the page populates a grid with all relevant voucher details, including its name, description, pricing, status, and audit information (such as who created it and when it was last updated).
5. Error Handling: If the voucher cannot be found or an error occurs, the system displays a clear message to the user.
6. Action: The user can click the "Edit" button at any time to navigate to the modification screen if changes are required.

1.3 Key Concepts

- Flexible Voucher: A versatile voucher product that allows for custom pricing, specific redemption locations, and eligibility rules.
- Open Price: A setting that allows staff to define a custom value for the voucher at the point of sale, rather than being restricted to a pre-set amount.
- Audit Fields: Automatically generated data points (Created By, Created At, Updated By, Updated At) that track the history and management of the voucher record.
- Redemption Logic: Rules governing where a voucher can be used (Location Fields) and when it is valid (Expiry and Valid From/Until fields).
-

Membership Restriction: An optional setting that limits the use of a voucher to specific customer loyalty groups or membership tiers.

1.4 Business Value

This feature improves operational efficiency by providing a single source of truth for voucher details. By clearly displaying complex rules—such as the difference between the price paid and the redemption value, or specific location restrictions—it reduces the risk of errors during the sales process. Furthermore, the inclusion of audit logs ensures accountability and transparency, allowing managers to easily track who created or modified voucher configurations.

2. Logic

2.1 Overview

The "Detail Flexible Voucher Page" feature allows users to view comprehensive information about a specific flexible voucher product. When a user navigates to the voucher details page, the system automatically retrieves the relevant data from our database and populates the screen with all necessary product attributes, such as pricing, validity periods, and status.

2.2 Step-by-Step Flow

1. Page Initialization: When a user opens the voucher details page, the system identifies the specific voucher ID.
2. Data Retrieval: The system sends a request to the server to fetch all stored information associated with that unique voucher ID.
3. Data Validation: The system confirms that the data has been successfully retrieved from the server.
4. Field Population: The system maps the retrieved information into the corresponding fields on the screen (such as the voucher name, description, base value, and status).
5. Display: The page renders the complete voucher profile for the user to review.

2.3 Key Concepts

- Flexible Voucher: A versatile voucher product type within the Lumi ERP system that can be configured with specific values, validity dates, and usage rules.
- Data Mapping: The process of taking raw information from our database and placing it into the correct, labeled fields on the user interface so it is easy to read.
- Voucher ID: A unique identifier used by the system to ensure that the correct voucher details are displayed when a user selects a specific product.

2.4 Business Value

This feature provides a centralized and reliable way for staff to verify the details of flexible vouchers. By automating the display of product information—including pricing, location rules, and validity—the system reduces manual lookup time, minimizes the risk of human error, and ensures that customer-facing voucher information is always consistent with the backend records.

3. Data

3.1 Overview

The "Detail Flexible Voucher Page" feature allows users to view comprehensive information about a specific flexible voucher product within the Lumi ERP system. This page acts as a dedicated information hub, ensuring that staff can quickly access the details, status, and monetary value of any flexible voucher by its unique identifier.

3.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view a specific voucher using its unique ID.
2. Data Retrieval: The system searches the database for a record that matches the provided ID and confirms that the product is categorized as a "flexible" voucher.
3. Validation: If the system cannot find a matching flexible voucher, it triggers an error message to notify the user that the product does not exist or is not a flexible type.
4. Data Formatting: Once the record is found, the system organizes the raw data into a clear, readable format, grouping the monetary amount and currency together.
5. Display: The finalized voucher details are presented to the user.

3.3 Key Concepts

- Flexible Voucher: A specific type of product within the ERP that allows for variable usage or value, distinct from standard fixed-value products.
- Unique Identifier (ID): A specific code assigned to each voucher that ensures the system retrieves the exact product requested.
- Data Mapping: The process of taking raw system information and organizing it into a user-friendly structure for the screen.

3.4 Business Value

This feature provides a reliable and efficient way to manage flexible voucher inventory. By centralizing the details of these products, the system reduces manual lookup time and prevents errors by ensuring that only valid, flexible

vouchers are displayed. This clarity helps staff manage product offerings accurately and improves the overall efficiency of the voucher management process.

BUSINESS REQUIREMENTS DOCUMENT

Warehouse History

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Warehouse History feature provides a clear, searchable log of all stock movements for a specific product. It allows users to see exactly how and when inventory levels have changed across different warehouse locations, helping to maintain accurate stock records and improve accountability.

1.2 Step-by-Step Flow

1. Automatic Loading: When you open the product history page, the system automatically retrieves and displays the full list of stock transactions for that product.
2. Applying Filters: You can narrow down the list using the filter bar at the top of the screen. You can filter by:

* Warehouse: Select a specific location or view all.

* Transaction Type: Filter by the nature of the movement (e.g., deliveries or imports).

* Date Range: Specify a "From" and "To" date to view activity within a certain timeframe.

* User: Search for records created by a specific person or role.

3. Search Execution: After adjusting your filters, click the "Search" button to refresh the table with the relevant data.
4. Reviewing Details: The table displays the history in chronological order, showing the date, warehouse, transaction type, the amount of stock added or removed, any relevant notes, and the user who recorded the change.

1.3 Key Concepts

- Stock Activity: A record of any event that increases or decreases the quantity of a product in a warehouse.
- Transaction Type: The category of the movement, which helps identify if the change was due to a purchase, a sale, or an internal adjustment.
- Quantity Changed: The specific number of items added (positive) or removed (negative) during a transaction.
- Filter Bar: A set of controls that allows you to refine the displayed data to find specific information quickly.

1.4 Business Value

- Improved Accountability: By tracking who created each record and including descriptive notes, the system ensures there is a clear audit trail for every inventory change.
- Operational Transparency: Warehouse managers can quickly investigate stock discrepancies by reviewing the history of specific products across different locations.
-

Efficient Reporting: The ability to filter by date and transaction type allows staff to generate quick insights into stock movement trends without needing to manually sort through large amounts of data.

2. Logic

2.1 Overview

The Warehouse History feature provides a transparent audit trail for your inventory. By viewing the history of a specific product, you can see exactly how its stock levels have changed over time across different warehouse locations. This feature ensures that every adjustment to your inventory is recorded, helping you maintain accurate stock counts and accountability.

2.2 Step-by-Step Flow

1. Trigger: When you open the product details page, the system automatically initiates a request to retrieve the stock history for that specific item.
2. Data Retrieval: The system searches the database for all recorded activities associated with that product, organizing them from the most recent to the oldest.
3. Formatting: The system gathers the relevant details for each activity—such as the date, the warehouse involved, the type of change, the quantity adjusted, and the user responsible.
4. Display: This information is mapped directly to your screen, presenting a clear, chronological list of all stock movements for the product.

2.3 Key Concepts

- Stock Activity: A record of any event that changes the quantity of a product, such as incoming shipments or outgoing orders.
- Change Type: A label describing the nature of the inventory adjustment (e.g., restock, sale, or manual correction).
- Quantity Changed: The specific number of units added to or removed from the warehouse inventory during a single transaction.
- Audit Trail: The collection of historical data that allows you to track who performed an action and when it occurred.

2.4 Business Value

This feature significantly improves inventory management by providing full visibility into stock fluctuations. By tracking these changes, your team can quickly identify the source of inventory discrepancies, verify the accuracy of warehouse operations, and maintain a reliable record of product movement. This level of detail is essential for

troubleshooting stock issues and ensuring that your inventory data remains trustworthy for daily operations and reporting.

3. Data

3.1 Overview

The Warehouse History feature provides a comprehensive audit trail for all stock movements within the Lumi ERP system. It automatically records every change in inventory levels—whether caused by customer orders, internal transfers, or manual adjustments—and stores the details in a permanent log. This allows your team to view the complete lifecycle of a product's stock levels across different warehouse locations.

3.2 Step-by-Step Flow

1. Automatic Recording: Whenever a stock level is adjusted, the system automatically captures the details of the change, including the product involved, the specific warehouse, the amount of the change, and who performed the action.
2. Data Storage: The system saves the "before" and "after" quantities, the reason for the change, and a timestamp, creating a reliable record of the event.
3. Product-Level Auditing: Users can view a chronological history for a specific product, showing exactly how its stock has moved across various warehouses over time.
4. Warehouse-Level Auditing: Users can view a chronological history for a specific warehouse, showing all stock activity for every product stored at that location.

3.3 Key Concepts

- Stock Movement: Any event that results in a change to the quantity of a product, such as receiving new inventory, shipping an order, or correcting a count.
- Audit Trail: A secure, chronological record that tracks the history of changes, providing transparency and accountability for inventory management.
- Quantity Delta: The specific amount by which the stock increased or decreased during a single transaction.
- Reference ID: A link to the original transaction (such as an order number) that triggered the stock change, allowing for easy cross-referencing.

3.4 Business Value

- Improved Accountability: By logging which user performed a stock adjustment and when, you can easily identify the source of any inventory discrepancies.
-

Enhanced Troubleshooting: If stock levels appear incorrect, staff can review the history log to see exactly when and why the numbers changed, significantly reducing time spent on manual investigations.

- Operational Transparency: Managers gain clear visibility into how products are moving through the supply chain, helping to identify trends and optimize warehouse performance.
- Regulatory Compliance: Maintaining a detailed history of inventory changes is essential for accurate reporting and meeting standard business auditing requirements.

BUSINESS REQUIREMENTS DOCUMENT

Warehouse Stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Warehouse Stocks feature provides a centralized view of inventory levels for a specific product across all company warehouse locations. It allows users to monitor stock availability, track items in transit, and manage reorder thresholds (minimum and maximum stock levels) to ensure optimal inventory management.

1.2 Step-by-Step Flow

1. Page Initialization: When you open the page, the system automatically retrieves the latest stock data for the selected product from all warehouses.
2. Filtering: You can narrow down the list of warehouses using the filter bar (by warehouse name, code, or specific warehouse selection). Clicking the "Search" button applies these filters to the table.
3. Data Review: The table displays detailed metrics for each location, including current stock, available stock, reserved items, and items currently in transit.
4. Bulk Editing: By clicking the "Edit" button, you can toggle the table into an editable mode. This allows you to update the "Min Qty" and "Max Qty" settings for multiple warehouses simultaneously.
5. Validation: As you update these quantities, the system automatically checks that the values are not negative and that the maximum quantity is not set lower than the minimum quantity, ensuring data integrity.

1.3 Key Concepts

- Available Quantity: The stock currently on hand that is free to be allocated to new orders, excluding items already reserved.
- Reserved Quantity: Stock that has been committed to existing customer orders and is no longer available for sale.
- In Transit: Stock that is currently being moved to a warehouse (e.g., from a supplier or another branch) but has not yet been officially received into the inventory.
- Min/Max Qty: Thresholds used to manage inventory levels; the "Min" triggers reorder alerts, while the "Max" helps prevent overstocking.
- Average Cost: The calculated average purchase price per unit for the stock held in a specific warehouse.

1.4 Business Value

This feature empowers inventory managers to make informed replenishment decisions by providing real-time visibility into stock distribution. By enabling bulk updates to minimum and maximum stock levels, the system

reduces manual administrative effort and helps prevent stockouts or excess inventory, ultimately improving operational efficiency and cash flow management.

2. Logic

2.1 Overview

The Warehouse Stocks feature provides a comprehensive view of a specific product's inventory levels across all company warehouses. It allows users to see not only how much stock is currently on hand, but also how that stock is allocated (e.g., reserved or in transit) and the associated financial value, helping teams make informed decisions about stock replenishment and distribution.

2.2 Step-by-Step Flow

1. Request Initiation: When a user views a product page, the system automatically requests stock data for that specific product.
2. Data Retrieval: The system gathers information from both the product inventory records and the warehouse directory to ensure all locations are accounted for.
3. Calculation: The system performs real-time calculations to determine the total value of the stock in each warehouse (by multiplying quantity by average cost) and calculates the grand total of all inventory across the entire organization.
4. Display: The processed data is presented in a clear table format, showing individual warehouse breakdowns alongside the calculated summary totals.

2.3 Key Concepts

- Inventory Quantity: The total amount of a product currently held in a specific warehouse.
- Available Quantity: The portion of stock that is not reserved and is ready for immediate sale or use.
- Reserved Quantity: Stock that has been set aside for specific orders or commitments.
- In-Transit Quantity: Stock that is currently being moved between locations and is not yet available for use.
- Min/Max Quantity: The defined thresholds for stock levels used to trigger replenishment alerts.
- Average Cost: The calculated unit cost of the product, used to determine the total financial value of the inventory.

2.4 Business Value

- Improved Inventory Visibility: Provides a single source of truth for stock levels across multiple locations, reducing the risk of overselling or stockouts.
-

Financial Clarity: Automatically calculates the total cost of inventory per warehouse, assisting with financial reporting and asset valuation.

- Operational Efficiency: By displaying "Available" versus "Reserved" stock, warehouse managers can quickly identify which items are ready for shipment without manual cross-referencing.
- Proactive Replenishment: With clear visibility into minimum and maximum stock levels, teams can better manage supply chain timing and avoid unnecessary storage costs.

3. Data

3.1 Overview

The Warehouse Stocks feature provides a comprehensive view of a specific product's inventory levels across all your warehouse locations. It allows you to see exactly how much stock is on hand, reserved, or currently in transit, along with the associated costs. This gives you a clear picture of your inventory distribution and helps you monitor stock levels against your defined minimum and maximum thresholds.

3.2 Step-by-Step Flow

1. Request: You select a specific product to view its stock distribution.
2. Data Retrieval: The system gathers all inventory records for that product, linking them to their respective warehouse names and codes.
3. Calculation: The system calculates the total value of the stock in each warehouse and aggregates the total quantity across all locations.
4. Presentation: The information is organized into a clear list, showing individual warehouse details alongside a summary of the total quantity available for that product.

3.3 Key Concepts

- Available Quantity: The stock currently on hand that is ready to be sold or used.
- Reserved Quantity: Stock that has been set aside for existing orders or specific commitments.
- In-Transit Quantity: Stock that is currently being moved between locations or is on its way from a supplier.
- Min/Max Quantity: The established thresholds for your inventory; these help you identify when stock is running low or when you are overstocked.
- Average Cost: The calculated unit cost of the product, used to determine the total financial value of the stock held in each warehouse.

3.4 Business Value

-

Improved Inventory Visibility: Quickly identify which warehouses hold your stock, reducing the time spent searching for product availability.

- Better Decision Making: With clear visibility into reserved and in-transit items, you can make more informed decisions about replenishment and order fulfillment.
- Financial Oversight: By displaying the total cost per warehouse, you can easily track the capital tied up in inventory across your network.
- Proactive Stock Management: Comparing current levels against your minimum and maximum quantities helps prevent stockouts and avoids unnecessary overstocking.

BUSINESS REQUIREMENTS DOCUMENT

Store Stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Store Stocks" feature provides a centralized view of how a specific product is distributed across your various store locations. It allows you to monitor inventory levels, track costs, and manage stock thresholds (minimum and maximum quantities) for each store directly from the dashboard.

1.2 Step-by-Step Flow

1. Initial Load: When you open the page, the system automatically retrieves the current stock data for the selected product and populates a list of all available stores.
2. Filtering: You can narrow down the list by selecting a specific store, searching by name or store code, or toggling a view to see only relevant stock conditions. Clicking "Search" updates the table based on your criteria.
3. Viewing Data: The table displays key metrics for each store, including current quantity, reserved stock, items in transit, and financial data like average and total costs.
4. Editing Thresholds: If you need to adjust stock management settings, click the "Edit" button. This turns the "Min Qty" and "Max Qty" columns into editable fields.
5. Saving Changes: After updating the desired values, click "Save" to commit your changes to the system. You can also click "Cancel" at any time to discard any unsaved edits.
6. Navigation: If the list of stores is long, you can use the pagination controls at the bottom to move between pages. You can also quickly jump to QR code or barcode printing tools from the header.

1.3 Key Concepts

- Min/Max Qty: The minimum and maximum stock levels defined for a product at a specific store, used to help manage replenishment and inventory health.
- Reserved Stock: Items that are currently allocated to orders but have not yet left the store.
- In Transit: Items that have been ordered or transferred but have not yet arrived at the store.
- Average/Total Cost: Financial metrics that calculate the value of the stock currently held at each location.
- Pagination: A navigation tool that breaks large lists of data into smaller, manageable pages.

1.4 Business Value

- Improved Inventory Control: By setting and monitoring minimum and maximum stock levels, you can prevent stockouts and avoid overstocking at individual locations.
-

Operational Efficiency: The ability to filter and search through store data allows staff to quickly locate specific inventory information without manual searching.

- Financial Visibility: Real-time access to total cost data per store helps management make informed decisions regarding stock distribution and capital allocation.
- Streamlined Workflow: Integrated access to QR and barcode tools ensures that staff can manage labeling and inventory tracking from a single, unified screen.

2. Logic

2.1 Overview

The Store Stocks feature provides a centralized view for monitoring inventory levels across different store locations for a specific product. It allows users to view real-time stock data, filter results by store or product details, and manage inventory thresholds (minimum and maximum quantities) directly within the interface.

2.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves the current stock levels for the product and populates a list of all available stores to be used as filter options.
2. Filtering: Users can narrow down the stock list by applying filters such as Store Name, Store Code, or specific stock visibility settings. Clicking "Search" updates the table to display only the relevant records.
3. Navigation: If there are many records, users can navigate through pages. The system maintains the active filters while loading the requested page of data.
4. Editing: Users can modify the minimum and maximum quantity thresholds for one or more stores.
5. Validation & Saving: Upon clicking "Save," the system performs a check to ensure that no minimum quantity exceeds its corresponding maximum quantity. If valid, the changes are saved in bulk, the table refreshes with the updated data, and the view returns to read-only mode.

2.3 Key Concepts

- Stock Thresholds: The minimum and maximum quantity levels defined for a product at a specific store, used to help manage inventory replenishment.
- Bulk Update: The ability to modify multiple stock records at once and save them in a single action, rather than updating each store individually.
- Data Filtering: Tools that allow users to isolate specific stock information based on store identity or product attributes.
-

Pagination: A method of breaking large lists of stock data into smaller, manageable pages to improve performance and readability.

2.4 Business Value

This feature streamlines inventory management by providing a clear, actionable view of stock distribution. By allowing users to adjust min/max thresholds directly, the system helps prevent stockouts and overstocking, ensuring that inventory levels remain optimized across all store locations. The bulk-update capability significantly reduces the administrative effort required to maintain accurate stock settings.

3. Data

3.1 Overview

The Store Stocks feature provides a clear, real-time view of inventory levels for a specific product across all your business locations. It allows staff to quickly see how many units of a product are available at each individual store, as well as the total quantity available across the entire company.

3.2 Step-by-Step Flow

1. Page Initialization: When you open the product detail page, the system automatically retrieves the current stock levels for that specific item.
2. Data Aggregation: The system calculates the total quantity of the product across all locations to provide an immediate summary.
3. Displaying Details: The system populates a table showing the breakdown of stock by store name, the specific quantity at each location, and the date the information was last updated.
4. Filtering: The system retrieves a complete list of all your stores, which populates a filter dropdown menu, allowing you to easily narrow down the stock view to specific locations.

3.3 Key Concepts

- Stock Level: The current count of a specific product held at a particular store location.
- Total Quantity: The sum of all stock for a single product across every store in the network.
- Store Filter: A selection tool that allows users to view inventory data for specific locations rather than the entire list.
- Last Updated: A timestamp indicating when the inventory count for a specific store was most recently recorded.

3.4 Business Value

This feature improves operational efficiency by eliminating the need to manually check inventory across different locations. By providing a centralized, accurate view of stock levels, your team can make faster decisions regarding product transfers, restock orders, and customer inquiries, ultimately ensuring that products are available where customers need them most.

BUSINESS REQUIREMENTS DOCUMENT

Product History

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product History feature provides a comprehensive audit trail for any given product within the Lumi ERP system. It allows users to view a chronological list of all changes made to a product's settings and pricing, ensuring transparency and accountability regarding how product data has evolved over time.

1.2 Step-by-Step Flow

1. Accessing the Page: When a user navigates to the Product History view for a specific item, the system automatically triggers a request to retrieve the full history log for that product.
2. Data Retrieval: The system fetches all recorded changes, including timestamps, the user who performed the update, and the specific product details at that moment.
3. Displaying the Log: The information is presented in a clear, tabular format. Each row represents a single point in time when a change was saved.
4. Reviewing Details: Users can scan the table to see historical values for pricing (Company Supply, Wholesale, Supply, and Retail), as well as status flags like whether the item was active, tracked for inventory, or part of a bundle.
5. Contextual Guidance: For specific fields like "Supply Price" and "Track," users can hover over informational icons to see helpful definitions, such as clarifying that "Track" determines whether the system automatically updates stock levels during sales.

1.3 Key Concepts

- Audit Trail: A chronological record that tracks who changed what and when, providing a reliable history of product modifications.
- Supply Price: The cost at which the store purchases the item from a supplier, inclusive of tax.
- Company Supply Price: The base purchase price from the supplier, also inclusive of tax, used for internal cost tracking.
- Tracking: A setting that determines if the system should automatically manage inventory levels for an item; this is typically enabled for physical goods and disabled for services.
- Bundle: A flag indicating if the product is sold as a collection of items rather than a single unit.

1.4 Business Value

This feature is essential for maintaining data integrity and operational oversight. By providing a clear history of price adjustments and configuration changes, it helps managers:

- Troubleshoot Discrepancies: Quickly identify when and why a price or setting was changed.
- Improve Accountability: See exactly which user performed an update, which is vital for team coordination.
- Support Decision Making: Analyze past pricing strategies to inform future adjustments, ensuring that the business maintains accurate records for both financial reporting and inventory management.

2. Logic

2.1 Overview

The Product History feature provides a transparent audit trail for any given product within the Lumi ERP system. By accessing this view, users can see a chronological list of all modifications made to a product's details, including price adjustments, warranty changes, and status updates. This ensures that team members can easily track how and when a product's information has evolved over time.

2.2 Step-by-Step Flow

1. Initiation: When a user navigates to the product history page, the system automatically triggers a request to retrieve the full change log for that specific product.
2. Data Retrieval: The system fetches the historical records, which include details such as who made the change, when it occurred, and the specific values (like prices or status flags) at that time.
3. Data Processing: The system organizes the raw data into a clear, readable format, ensuring that every change is correctly labeled for the user.
4. Display: The processed information is rendered into a table on the screen, allowing the user to review the complete history of the product.
5. Error Handling: If the system is unable to retrieve the data, a notification will appear to inform the user that the history could not be loaded.

2.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific product.
- Change Log: A list of modifications, including updates to pricing (wholesale, retail, supply), status (active/inactive), and product attributes (warranty, bundle status, tracking).
- User Attribution: The system records "who" performed the update, ensuring accountability and clarity regarding changes made to product data.

2.4 Business Value

This feature enhances operational transparency and data integrity. By maintaining a clear history of product changes, businesses can:

- Improve Accountability: Easily identify who updated product information and when.
- Support Decision Making: Review past pricing strategies and attribute changes to better inform future adjustments.
- Simplify Troubleshooting: Quickly identify when a specific change (such as a price or status update) occurred if an issue arises, reducing the time spent investigating data discrepancies.

3. Data

3.1 Overview

The Product History feature provides a comprehensive audit trail for any product within the Lumi ERP system. It allows users to view a chronological list of all modifications made to a product's details, such as pricing updates, warranty changes, and status toggles. By displaying who made a change and when, this feature ensures full transparency and accountability for all product-related data.

3.2 Step-by-Step Flow

1. Request: A user selects a specific product to view its history.
2. Retrieval: The system searches the database for all recorded changes associated with that specific product.
3. Sorting: The system organizes these records starting with the most recent change, ensuring the latest updates appear at the top of the list.
4. Display: The system presents the data in a clear format, showing the date of the change, the person responsible, and the updated values for pricing, warranty, and product settings (such as whether the item is active, tracked, or part of a bundle).

3.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific product.
- Product History: A detailed log capturing changes to key business attributes, including various price points (supply, wholesale, retail) and operational flags.
- Chronological Ordering: The practice of listing records by date, ensuring users can easily track the evolution of a product over time.

3.4 Business Value

-

Accountability: By tracking who updated a product and when, teams can easily identify the source of data changes, reducing errors and confusion.

- Informed Decision Making: Having access to historical pricing and configuration data allows managers to analyze past trends and make better-informed adjustments to current product strategies.
- Operational Transparency: This feature eliminates guesswork regarding product status, ensuring that all team members are aligned on the current state and history of any item in the inventory.

BUSINESS REQUIREMENTS DOCUMENT

Stock History

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock History feature provides a detailed audit trail of all inventory changes for a specific product. It allows users to view a chronological list of stock movements, helping them understand when, where, and why stock levels changed, as well as who performed the adjustment.

1.2 Step-by-Step Flow

1. Initial Load: When you open the Stock History page for a product, the system automatically retrieves the full history of stock movements for that item and populates a list of available stores for the filter menu.
2. Filtering: You can narrow down the results by selecting a specific store, entering a transaction type, choosing a date range, or searching by the user who created the record.
3. Search Execution: Once you have set your desired criteria, clicking the "Search" button updates the table to display only the records that match your filters.
4. Reviewing Data: The table displays the history in a clear format, showing the date, store location, type of transaction, the specific quantity change (with clear positive or negative indicators), any associated notes, and the staff member responsible.

1.3 Key Concepts

- Stock Movement: Any event that increases or decreases the inventory count for a product (e.g., a new shipment or a customer sale).
- Audit Trail: A record of "who, what, and when" regarding inventory changes, which ensures accountability and helps troubleshoot stock discrepancies.
- Filtered Search: The ability to isolate specific data points—such as viewing only "restock" events at a specific store within a specific week—to make large amounts of data easier to manage.
- Signed Quantity: A display method where increases are shown with a plus sign (e.g., +5) and decreases with a minus sign (e.g., -2), allowing for immediate visual recognition of the stock impact.

1.4 Business Value

This feature is essential for maintaining accurate inventory records. By providing a transparent history of stock adjustments, it enables managers to:

* Identify Discrepancies: Quickly spot unauthorized or incorrect stock changes.

* Improve Forecasting: Analyze trends in stock movement types (like sales vs. returns) to better plan future inventory needs.

* Enhance Accountability: Maintain a clear record of staff activity, which is vital for operational oversight and loss prevention.

2. Logic

2.1 Overview

The Stock History feature provides a clear, chronological view of how a specific product's inventory levels have changed over time. Users can view a detailed log of stock movements—such as additions or subtractions—and use various filters to pinpoint specific transactions, helping them maintain accurate inventory records and audit trail transparency.

2.2 Step-by-Step Flow

1. Initial Page Load: When you open the Stock History page for a product, the system automatically retrieves the full list of available stores to populate the "Store" filter dropdown.
2. Displaying Data: Simultaneously, the system fetches the complete stock history for that product and displays it in a table, showing details like the date, store location, type of movement, quantity changed, and who recorded the entry.
3. Applying Filters: You can narrow down the results by selecting specific criteria, such as a particular store, movement type, date range, or the person who created the entry.
4. Updating Results: Once you click the "Search" button, the system refreshes the table to show only the records that match your selected filters.

2.3 Key Concepts

- Stock Movement: A record of any event that changes the quantity of a product, such as a restock, a sale, or an adjustment.
- Filter Criteria: The specific parameters (Store, Type, Date Range, Created By) used to refine the list of history records.
- Audit Trail: The ability to see "who" performed an action and "when" it occurred, which is captured in the "Created By" and "Date" fields.
- Quantity Change: The net impact on stock levels, clearly distinguishing between increases and decreases for each transaction.

2.4 Business Value

This feature improves inventory accountability by providing a transparent history of stock adjustments. By allowing users to filter by store, date, or user, the system enables quick troubleshooting of inventory discrepancies, simplifies

end-of-period reporting, and ensures that all stock changes are documented and easily searchable for auditing purposes.

3. Data

3.1 Overview

The Stock History feature provides a transparent audit trail for product inventory. It allows users to view a detailed log of every stock movement for a specific product, including when the change occurred, which store was involved, the quantity adjusted, and who performed the action. This feature ensures accountability and helps users track inventory fluctuations over time.

3.2 Step-by-Step Flow

1. Initial Page Load: When a user opens the Stock History page for a specific product, the system automatically retrieves the full history of stock movements for that item.
2. Populating Filters: Simultaneously, the system fetches a list of all available stores to populate the "Store" filter dropdown, allowing users to narrow their search later.
3. Applying Filters: Users can refine the list by selecting specific criteria, such as a particular store, the type of movement, a date range, or the user who created the record.
4. Triggering Search: Once the user clicks the "Search" button, the system applies these filters to the database and updates the results table with the relevant records.
5. Sorting Data: Users can click on table column headers to sort the history (e.g., by date or quantity), which instantly refreshes the view to display the data in the desired order.

3.3 Key Concepts

- Stock Movement: Any event that changes the inventory level of a product, categorized by type (e.g., additions or deductions).
- Audit Trail: A chronological record of changes, including the date, the specific store location, and the individual responsible for the entry.
- Dynamic Filtering: The ability to narrow down large volumes of data using specific parameters like date ranges or store locations to find relevant information quickly.
- Sortable Data: The ability to organize the history list by different attributes, such as the most recent changes or the largest quantity adjustments.

3.4 Business Value

-

Accountability: By tracking who created each stock entry and when, the business can easily identify the source of inventory discrepancies.

- Operational Visibility: Managers gain a clear understanding of how stock levels fluctuate across different store locations, supporting better replenishment and planning decisions.
- Efficient Troubleshooting: The ability to filter and sort historical data allows staff to quickly investigate specific inventory issues without manually searching through paper logs or disconnected records.

BUSINESS REQUIREMENTS DOCUMENT

Service Product Add Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Product Add Page is a dedicated interface within the Lumi ERP system designed to help users efficiently create and manage new service offerings. This page allows users to input essential product details, configure pricing structures, and define tax settings, ensuring that all service information is accurately captured and stored in the system.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically fetches necessary configuration data (such as tax rates and units of measure) to populate the dropdown menus.
2. Data Entry: The user fills out the product details, including the name, description, and any relevant categorization (Type or Tag). If a specific type or tag does not exist, the user can create it on the fly using the provided buttons.
3. Pricing Configuration: The user enters the service price. They can toggle an "Including Tax" checkbox to specify whether the entered price already accounts for tax.
4. Automatic Calculation: The system performs a real-time calculation:

* If "Including Tax" is unchecked, the system treats the price as the base amount.

* If "Including Tax" is checked, the system automatically calculates the pre-tax price by stripping the tax amount from the total.

5. Submission: Once the user clicks "Save," the system validates the information and creates the new service product.
6. Navigation: Upon a successful save, the user is automatically redirected to the new product's detail page to review the entry.

1.3 Key Concepts

- Service Product: A non-physical offering (e.g., consulting, maintenance) that can be priced and tracked within the ERP.
- Including Tax Toggle: A feature that determines how the system interprets the price input, ensuring accurate financial reporting regardless of whether the user enters a gross or net amount.
- Dynamic Pricing: The system’s ability to automatically derive the pre-tax price based on the user's tax settings, reducing manual calculation errors.
-

On-the-fly Creation: The ability to add new categories (Types or Tags) directly from the product page without needing to navigate to a separate settings menu.

1.4 Business Value

- Efficiency: By automating tax calculations and allowing for the creation of new categories directly within the form, the system reduces the time and effort required to add new services.
- Data Accuracy: Real-time calculation of pre-tax pricing ensures that financial data remains consistent and reliable for accounting purposes.
- User Experience: The intuitive layout and seamless navigation to the detail page after saving provide a smooth, professional workflow for staff managing the product catalog.

2. Logic

2.1 Overview

The Service Product Add Page allows you to define new service offerings within the Lumi ERP system. This feature enables you to input service details, set pricing, and manage tax configurations. The system is designed to handle pricing flexibility, automatically calculating the tax-exclusive price based on your preferences so that your financial records remain accurate.

2.2 Step-by-Step Flow

1. Initialization: When you open the "Add Service Product" page, the system automatically retrieves necessary configuration data, such as available tax rates and units of measure, to populate your dropdown menus.
2. Data Entry: You enter the service name, description, and the price. You also indicate whether the price you entered already includes tax by toggling the "Including Tax" option.
3. Automated Calculation: When you click "Save," the system checks your tax setting. If the price includes tax, the system automatically strips the tax amount to determine the base (tax-exclusive) price. If the price does not include tax, the system uses your entered amount as the base price.
4. Submission: The system saves the complete service record, including the name, description, total price, and the calculated tax-exclusive price, to the database.
5. Confirmation: Upon a successful save, the system confirms the creation and directs you to the details page for the new service.

2.3 Key Concepts

- Service Product: A non-physical offering (such as consulting or maintenance) that can be sold and tracked within the ERP.

- Including Tax: A setting that tells the system whether the price you provided is the final amount paid by the customer (inclusive) or the base amount before tax is applied (exclusive).
- Tax-Exclusive Price: The base price of a service before any applicable taxes are added; this is calculated automatically by the system to ensure consistent financial reporting.
- Metadata: Background information, such as tax rates, that the system loads automatically to ensure all dropdown menus and form fields are up-to-date.

2.4 Business Value

This feature streamlines the product creation process by removing the need for manual tax calculations. By automating the derivation of tax-exclusive pricing, the system reduces the risk of human error, ensures compliance with tax reporting requirements, and provides a consistent, efficient workflow for managing your service catalog.

3. Data

3.1 Overview

The Service Product Add page allows users to define and save new service offerings within the Lumi ERP system. This feature ensures that service details—such as the name, description, and pricing—are accurately captured and stored. A key component of this page is its intelligent handling of tax, which automatically calculates the base price of a service based on whether the user provides a tax-inclusive or tax-exclusive amount.

3.2 Step-by-Step Flow

1. Input Details: The user enters the service name, description, and the price into the form.
2. Tax Selection: The user indicates whether the entered price already includes tax by toggling the "Including Tax" option.
3. Submission: Upon clicking the "Save" button, the system processes the information.
4. Automated Calculation: The system determines the tax-exclusive price. If the price includes tax, it automatically strips the tax amount; if it does not include tax, the entered price is used as the base.
5. Record Creation: The system generates a unique identifier for the service, saves all details to the database, and confirms the creation.
6. Navigation: Once successfully saved, the application automatically redirects the user to the newly created service product's detail page.

3.3 Key Concepts

- Service Product: A non-physical offering (such as consulting or maintenance) that can be sold and tracked within the ERP.
- Tax-Inclusive Pricing: A pricing method where the final amount paid by the customer already contains the tax component.
- Tax-Exclusive Pricing: A pricing method where the tax is calculated and added on top of the base price.
- Automated Tax Handling: The system's ability to derive the base price (pre-tax) regardless of how the user chooses to input the final price, ensuring consistent financial reporting.

3.4 Business Value

This feature streamlines the administrative process of adding new services to the catalog. By automating the tax calculation logic, the system reduces the risk of manual entry errors and ensures that financial data remains accurate for accounting purposes. This allows staff to focus on defining service offerings quickly while maintaining high data integrity across the ERP.

BUSINESS REQUIREMENTS DOCUMENT

Service Product Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Product Detail Page provides a comprehensive, read-only view of a specific service offered by the business. This page allows users to review all relevant information regarding a service—including its pricing, tax configurations, and operational settings—in one centralized location. It is designed to ensure that staff can quickly verify service details before making any necessary updates.

1.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the page, the system automatically identifies the specific service product and retrieves its full profile from the database.
2. Loading State: While the information is being retrieved, the user sees a loading indicator to confirm the system is processing the request.
3. Data Display: Once loaded, the page displays the service information organized into logical sections:

* Header: Shows the service name, SKU, and a status badge.

* Details: Displays core information like the description, type, and tags.

* Tax: Lists all tax-related settings, including tax categories and accounting codes.

* Settings: Shows operational flags, such as whether the service is active and its estimated completion time.

* Store Pricing: Displays the base price and currency for the service.

* Changes: Provides an audit trail showing when the record was created or last updated.

4. Navigation: The user can return to the main list of services using the "Service Products" button or transition to an edit mode using the "Edit" button to make changes to the record.

1.3 Key Concepts

- Service Product: A specific offering within the ERP system that represents a service rather than a physical good.
- Read-Only View: A display format where information is presented for review without allowing direct modification, ensuring data integrity.
- Audit Trail: A record of "who and when" regarding the creation and modification of the service data, found in the "Changes" section.
- SKU (Stock Keeping Unit): A unique identifier used to track the specific service product within the system.

1.4 Business Value

This feature improves operational efficiency by providing a clear, standardized view of service data. By centralizing tax, pricing, and configuration details, it reduces the time staff spend searching for information across different screens. Furthermore, the inclusion of an audit trail ensures accountability and transparency, allowing managers to track when and how service details were last modified.

2. Logic

2.1 Overview

The Service Product Detail Page feature provides a centralized view for users to examine the complete profile of a specific service offered by the company. When a user selects a service, the system retrieves all relevant information—including pricing, tax details, and status—to ensure staff have a clear and accurate understanding of the service's configuration.

2.2 Step-by-Step Flow

1. Initiation: When a user navigates to the detail page for a specific service, the system identifies the unique identifier for that service from the web address.
2. Data Retrieval: The system automatically requests the full record for that service from the database.
3. Tax Information Lookup: The system cross-references the service’s tax category to pull in the specific tax name and rate associated with that service.
4. Information Display: The system populates the page sections with the retrieved data, including the service description, pricing, tax details, current status, and the date of the last update.
5. Error Handling: If the system cannot locate the requested service, it will display an error message to inform the user that the information is unavailable.

2.3 Key Concepts

- Service Product: A non-physical offering (such as a consultation or maintenance plan) managed within the ERP system.
- SKU (Stock Keeping Unit): A unique code used to identify and track a specific service product.
- Tax Category: A classification that determines the tax rate applied to a service.
- Base Price: The standard cost of the service before any additional fees or discounts are applied.
- Status (Active/Inactive): A setting that indicates whether the service is currently available for sale or use.

2.4 Business Value

This feature ensures that employees have immediate access to consistent and accurate service information. By consolidating pricing, tax, and status details into one view, the system reduces the risk of manual errors during sales or administrative tasks and provides a reliable "source of truth" for all service-related inquiries.

3. Data

3.1 Overview

The Service Product Detail Page feature provides a comprehensive view of a specific service offered by the business. It allows users to see all relevant information for a single service in one place, including its description, pricing, tax classification, and current status. This ensures that staff have a clear and accurate understanding of the service details whenever they need to review or manage them.

3.2 Step-by-Step Flow

1. Request Initiation: When a user navigates to a specific service product page, the system identifies the unique identifier for that service from the web address.
2. Data Retrieval: The system searches the database for the primary service record associated with that identifier.
3. Context Gathering: If the service is found, the system automatically pulls in the associated tax information (such as the tax category name and rate) to ensure the financial details are complete.
4. Data Consolidation: The system combines the service details, pricing, tax settings, and the most recent update timestamp into a single, organized summary.
5. Display: The consolidated information is sent to the page, where it populates the various sections—such as the pricing, tax, and status areas—for the user to view. If the service cannot be found, the system displays a clear "not found" message.

3.3 Key Concepts

- Service Product: A specific offering provided by the business that has its own unique identifier, description, and pricing.
- Tax Category: A classification assigned to a service that determines the specific tax rate applied to it.
- SKU (Stock Keeping Unit): A unique code used to identify and track a specific service within the system.
- Audit Information: A record of when the service details were last modified, helping users track the history of changes.

3.4 Business Value

This feature centralizes critical service information, reducing the time staff spend searching for details across different systems. By automatically linking tax rates and pricing to the service, it minimizes the risk of manual errors during billing or reporting. Additionally, providing a clear "last modified" date ensures that users are always working with the most current and accurate service data.

BUSINESS REQUIREMENTS DOCUMENT

Vouchers - Edit Flexible Voucher Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Edit Flexible Voucher" page allows authorized users to update the details of an existing flexible voucher product within the Lumi ERP system. This interface ensures that all relevant information—such as naming, validity periods, location restrictions, and member eligibility—can be adjusted to reflect current business requirements.

1.2 Step-by-Step Flow

1. Page Load: When the user navigates to the edit page, the system automatically retrieves the current data for the specific voucher and populates all form fields with the existing values.
2. Data Modification: The user updates the necessary fields, including the SKU, name, description, expiration settings, product conditions, and location or member restrictions.
3. System-Managed Fields: Certain fields, such as the price (excluding tax) and the total voucher value, are displayed as read-only to ensure data integrity, as these are managed by the system.
4. Saving Changes: Once the user is satisfied with the updates, they click the "Save" button. The system sends the updated information to the database and redirects the user back to the voucher's detail page.
5. Cancellation: If the user decides not to proceed with the changes, they can click the "Cancel" button to discard all edits and return to the voucher's detail page without modifying any data.

1.3 Key Concepts

- Flexible Voucher: A versatile voucher product that allows for configurable pricing, validity, and usage rules.
- SKU (Stock Keeping Unit): A unique identifier used to track and manage the voucher product within the system.
- Open Price: A setting that, when enabled, allows the voucher to have a flexible or variable price rather than a fixed one.
- Read-only Fields: Information fields that are visible to the user but cannot be modified, as they are calculated or controlled by the system.
- Location/Member Restrictions: Configurable settings that define exactly where a voucher can be sold, issued, or redeemed, and whether it is exclusive to specific members.

1.4 Business Value

This feature provides the flexibility needed to manage promotional and financial products effectively. By allowing users to easily update voucher parameters, the business can respond quickly to changing market conditions, adjust expiration dates for seasonal campaigns, or refine the eligibility criteria for specific customer segments

without needing technical intervention. This ensures that voucher data remains accurate and aligned with current sales and marketing strategies.

2. Logic

2.1 Overview

The "Edit Flexible Voucher" feature allows administrators to update the details of an existing flexible voucher product within the Lumi ERP system. This ensures that voucher information—such as pricing, validity periods, and redemption locations—remains accurate and up-to-date.

2.2 Step-by-Step Flow

1. Page Initialization: When a user opens the edit page for a specific voucher, the system automatically retrieves the current data for that voucher using its unique identifier.
2. Data Population: The retrieved information is automatically mapped to the corresponding fields on the screen (e.g., Name, SKU, Price, and Validity dates), allowing the user to see the current settings.
3. User Modification: The user updates the necessary fields in the form to reflect the desired changes.
4. Submission: Upon clicking the "Save" button, the system collects the updated information from the form.
5. System Update: The system sends the updated data to the database to overwrite the previous voucher details.
6. Confirmation: Once the update is successfully processed, the user is automatically redirected back to the voucher's detail page to view the changes.

2.3 Key Concepts

- Flexible Voucher: A versatile voucher product type within the ERP that supports customizable pricing, expiration rules, and specific location-based usage.
- Unique Identifier (ID): A specific reference code used by the system to ensure the correct voucher is being edited.
- Data Mapping: The process of ensuring that information entered into a form field (like "Price") is correctly saved into the corresponding database field.
- Payload: The collection of all form data bundled together by the system to be sent to the server during the save process.

2.4 Business Value

- Operational Efficiency: Provides a streamlined interface for staff to quickly adjust voucher terms without needing technical intervention.
-

Data Accuracy: Ensures that critical business information, such as voucher validity and pricing, is consistently maintained and synchronized across the system.

- Flexibility: Allows the business to adapt voucher offerings in real-time to meet changing promotional needs or operational requirements.

3. Data

3.1 Overview

The "Edit Flexible Voucher" feature allows administrators to manage and update the details of existing flexible voucher products within the Lumi ERP system. This functionality ensures that voucher information—such as pricing, validity periods, and redemption locations—remains accurate and up-to-date as business requirements change.

3.2 Step-by-Step Flow

1. Page Load: When an administrator opens the edit page for a specific voucher, the system automatically retrieves the current details of that voucher using its unique identifier.
2. Data Population: The system maps the retrieved information into the corresponding fields on the screen (e.g., Name, SKU, Price, and Validity dates), allowing the user to see the current configuration.
3. User Modification: The administrator updates the necessary fields on the form.
4. Submission: Upon saving, the system sends the updated information to the database.
5. Confirmation: The system processes the update and returns a confirmation message to the user, indicating that the voucher details have been successfully modified.

3.3 Key Concepts

- Flexible Voucher: A versatile voucher product that can be configured with specific pricing, expiration rules, and location-based redemption settings.
- Unique Identifier: A specific reference code used by the system to ensure the correct voucher is being retrieved and updated.
- Data Mapping: The process of ensuring that information stored in the database correctly aligns with the fields displayed on the user interface.
- Redemption/Issue Locations: Specific business locations or branches where a voucher can be sold, issued, or redeemed by customers.

3.4 Business Value

-

Operational Agility: Allows staff to quickly adjust voucher terms (such as expiration dates or pricing) in response to marketing campaigns or changing business policies without needing technical support.

- Data Accuracy: By providing a structured interface for updates, the system ensures that voucher details remain consistent across the ERP, reducing the risk of errors during customer transactions.
- Improved Customer Experience: Ensures that redemption rules and validity periods are always current, preventing confusion or service issues when customers attempt to use their vouchers.

BUSINESS REQUIREMENTS DOCUMENT

Service Product Edit Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Product Edit page allows users to modify the details and pricing of an existing service within the Lumi ERP system. When a user navigates to this page, the system automatically retrieves the current information for the selected service and populates the form fields, ensuring that users can easily review and update specific attributes such as descriptions, pricing, and tax configurations.

1.2 Step-by-Step Flow

1. Page Initialization: Upon opening the page, the system identifies the specific service product and automatically fetches its current data from the database.
2. Data Population: The retrieved information is used to pre-fill all form sections, including the Info Card (name, SKU, description), Pricing Card (price), and Tax Card (tax settings and account codes).
3. User Modification: The user updates the necessary fields. The system performs real-time checks to ensure the name is provided and the price remains a positive value.
4. Saving Changes: Once the user clicks the "Save" button, the system submits the updated information to the server.
5. Navigation: Upon a successful save, the user is automatically redirected back to the main product list. If the user chooses to discard their changes, the "Cancel" button returns them to the previous screen without saving.

1.3 Key Concepts

- Info Card: A section containing core identification details for the service, such as its unique SKU, name, and descriptive information.
- Store Pricing Card: A dedicated area for managing the financial aspect of the service, specifically the price and tax inclusion settings.
- Tax Card: A specialized section for configuring tax-related settings, including tax types, account associations, and measurement units required for accurate financial reporting.
- Validation: Built-in safeguards that prevent errors, such as ensuring the product name is not left blank and that the price is not set to a negative number.

1.4 Business Value

This feature streamlines the maintenance of service offerings by providing a centralized, intuitive interface for updates. By pre-filling existing data, it reduces manual entry time and minimizes the risk of errors. Furthermore,

the built-in validation ensures that all service records remain consistent and accurate, which is critical for reliable financial tracking and tax compliance within the ERP.

2. Logic

2.1 Overview

The Service Product Edit feature allows users to modify the details and pricing of existing service products within the Lumi ERP system. This functionality ensures that service information, such as descriptions, tax settings, and pricing, remains accurate and up-to-date.

2.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the edit page for a specific service product, the system automatically retrieves the current record's information.
2. Form Population: The retrieved data is used to pre-fill all fields, including text boxes and dropdown menus (such as tax categories, account assignments, and product types), ensuring the user sees the most recent version of the product.
3. User Updates: The user modifies the necessary fields within the Info, Tax, Settings, or Pricing cards.
4. Validation: Upon clicking "Save," the system performs a check to ensure all mandatory fields—specifically the SKU, Name, Tax settings, and Price—are completed. If any required information is missing, the system displays an error message to the user.
5. Submission and Confirmation: If the data is valid, the system saves the changes. Once successfully updated, the user is automatically redirected to the Service Product Detail page to view the finalized changes.

2.3 Key Concepts

- Service Product: A specific service offering managed within the ERP, containing details like pricing, tax rules, and accounting codes.
- Form Validation: A safety check that prevents the system from saving incomplete or invalid data, ensuring data integrity.
- Pre-filling: The process of automatically populating form fields with existing data so the user only needs to change what is necessary rather than re-entering all information.
- Mandatory Fields: Specific pieces of information (SKU, Name, Tax, Other Tax, and Price) that must be provided for the system to process the update.

2.4 Business Value

This feature streamlines administrative tasks by providing a reliable and efficient way to maintain service catalogs. By allowing quick updates to pricing and tax configurations, the business can respond rapidly to market changes or regulatory updates, while the built-in validation reduces the risk of human error and ensures consistent data across the ERP.

3. Data

3.1 Overview

The Service Product Edit feature allows users to modify the details and pricing of existing service offerings within the Lumi ERP system. This functionality ensures that your service catalog remains accurate and up-to-date by providing a structured way to update key information, such as tax settings, pricing, and product categorization.

3.2 Step-by-Step Flow

1. Page Loading: When you navigate to the edit page for a specific service, the system automatically retrieves the current information for that product. This populates all fields and dropdown menus with the existing data so you can see exactly what is currently on file.
2. Data Modification: You can update the product's name, description, pricing, and various settings (such as tax codes, tags, and account associations) using the provided form fields and dropdowns.
3. Validation: When you click "Save," the system performs a check to ensure all mandatory information—specifically the SKU, Name, Tax settings, Other Tax settings, and Price—is present.
4. Error Handling: If any required information is missing, the system will display an error message, allowing you to correct the input before trying to save again.
5. Completion: Once the data is successfully validated and saved, the system updates the record with a new timestamp and redirects you to the product detail page to view your changes.

3.3 Key Concepts

- Service Product: A specific service offering in your catalog that includes pricing, tax configurations, and accounting details.
- Mandatory Fields: Essential pieces of information (SKU, Name, Tax, Other Tax, and Price) that must be provided for the system to process the update.
- Dropdown Population: The process of automatically filling selection menus with existing data, ensuring that you are choosing from valid, pre-defined options for categories like tax codes or product types.
- Validation: A built-in safety check that prevents incomplete or incorrect data from being saved to the system.

3.4 Business Value

This feature provides a reliable and efficient way to manage service pricing and tax compliance. By enforcing data validation, it reduces the risk of human error, ensuring that financial and tax-related information remains consistent across the ERP. This ultimately supports accurate reporting and seamless billing processes.

BUSINESS REQUIREMENTS DOCUMENT

Products Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Products Menu is a navigation component designed to help users easily access various product-related pages within the Lumi ERP system. It features an interactive "accordion" style menu that allows users to expand or collapse sub-categories, ensuring the interface remains clean while providing quick access to specific voucher types.

1.2 Step-by-Step Flow

1. Initial State: When the user accesses the system, the "Products" menu is visible and expanded by default, showing the available sub-menu options.
2. Interaction: The user can click on the "Products" menu item to toggle the sub-menu. A visual indicator (a chevron icon) updates to show whether the menu is currently open or closed.
3. Sub-Menu Selection: When expanded, the sub-menu displays three specific options: Standard, Batch, and Flexible.
4. Navigation: Clicking any of these sub-menu items triggers a navigation action to the corresponding page (Standard Voucher List, Batch Voucher List, or Flexible Vouchers Page).
5. Sticky Positioning: Once a user navigates to a product page, the sub-menu remains "sticky" at the top of the screen, positioned just below the main system header. This ensures that navigation remains accessible even as the user scrolls through long lists or pages.

1.3 Key Concepts

- Accordion Menu: A UI pattern that allows sections of content to be hidden or revealed by clicking a header, helping to save screen space.
- Sticky Positioning: A design feature that keeps a specific element (in this case, the sub-menu) fixed at the top of the browser window so it does not disappear when the user scrolls down.
- Active State: A visual highlight that indicates to the user which menu section is currently selected or in use.
- Chevron: A small arrow icon used to indicate that a menu item can be expanded or collapsed.

1.4 Business Value

This feature improves the user experience by organizing complex product navigation into a compact, intuitive format. By using a sticky sub-menu, we reduce the effort required for users to switch between different voucher types, as they do not need to scroll back to the top of the page to change their selection. This streamlined navigation supports higher efficiency for users managing daily ERP tasks.

BUSINESS REQUIREMENTS DOCUMENT

Main Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Main Menu is a persistent, "sticky" navigation bar located at the top of every page in the Lumi ERP system. It serves as the central hub for users to navigate between core business modules, manage their account settings, view notifications, and perform system-wide searches. Because it is "sticky," it remains visible at the top of the screen even as the user scrolls through long pages, ensuring constant access to essential tools.

1.2 Step-by-Step Flow

1. Session Verification: When a user loads any page, the system automatically checks if they are logged in. If the session is valid, the user's name is displayed; if not, the user is redirected to the login page.
2. Navigation: The user selects a top-level category (e.g., Customers, Products, Inventory). The system updates the view to display the specific sub-menu relevant to that selection.
3. Search: The user types a query into the search bar. To ensure system performance, the search only triggers after the user has finished typing (a short delay is applied).
4. Notifications: The user clicks the notification bell to toggle a dropdown list of alerts.
5. Profile Management: The user clicks their name to reveal a menu containing account settings and a logout option.
6. Logout: If the user selects "Logout," the system clears the session and returns them to the login page.

1.3 Key Concepts

- Sticky Header: A design approach where the navigation bar stays fixed at the top of the browser window, providing constant access to navigation regardless of how far down the page a user scrolls.
- Debounced Search: A performance optimization technique that waits for the user to stop typing for a brief moment before sending the search request to the server, preventing unnecessary system load.
- Session Management: The automated process of verifying a user's identity upon page load and handling secure sign-outs to protect company data.
- Contextual Sub-menus: Dynamic menus that change based on the primary category selected, keeping the interface clean by only showing relevant options.

1.4 Business Value

- Improved Efficiency: By keeping the navigation bar visible at all times, users can switch between business modules (like Finance or Inventory) instantly without needing to scroll back to the top of the page.
-

Enhanced User Experience: The search feature is optimized to be responsive without slowing down the system, and the clear separation of modules reduces clutter.

– Security and Control: Automated session checks ensure that only authorized users can access the ERP, while the centralized logout process ensures that user sessions are terminated correctly.

2. Logic

2.1 Overview

The Main Menu header is the primary navigation component for the Lumi ERP system. It is designed to ensure that only authenticated users can access the system while providing a personalized experience. The header automatically identifies who is logged in, displays their profile information, and provides a secure way to end their session.

2.2 Step-by-Step Flow

1. Session Verification: As soon as a page loads, the system automatically checks if the user has an active session.
2. Identity Retrieval: If the session is valid, the system retrieves the user's details—specifically their name, email, and assigned role—to display in the header.
3. Access Control: If the system cannot verify the user (or if the session has expired), it automatically redirects them to the login page to protect sensitive data.
4. Logout Process: When a user clicks the "Logout" button, the system invalidates their current session and redirects them back to the login page.

2.3 Key Concepts

– Session Verification: The automated background check that confirms a user’s identity and permissions every time they access a page.

– User Profile Mapping: The process of taking raw system data (such as a user's name and role) and displaying it clearly within the header interface.

– Secure Redirection: A safety mechanism that forces an unauthenticated user to the login screen, preventing unauthorized access to the ERP.

2.4 Business Value

– Enhanced Security: By automatically verifying sessions and handling logouts, the system ensures that only authorized personnel can interact with the ERP, reducing the risk of unauthorized access.

–

Improved User Experience: Users are greeted with their personalized information immediately upon loading a page, creating a seamless and professional interface.

– Operational Efficiency: The automated session management reduces the need for manual intervention, ensuring that users are always directed to the correct screen based on their login status.

3. Data

3.1 Overview

The Main Menu feature serves as the primary navigation header for the Lumi ERP system. Its main purpose is to identify the currently logged-in user and display a personalized greeting, ensuring that only authenticated users can access the system's features.

3.2 Step-by-Step Flow

1. Initialization: When a user opens any page in the ERP, the system automatically checks their current login status.
2. Verification: The system verifies the user's session in the background.
3. Access Control:

* If the session is valid, the system retrieves the user's name and displays it in the header.

* If the session is invalid or expired, the system automatically redirects the user to the Login page.

4. Display: Once verified, the header renders the Lumi ERP logo and a personalized "Welcome" message for the user.

3.3 Key Concepts

– Session Verification: A security check that confirms a user is currently logged in before allowing them to view the page content.

– Header Skeleton: A temporary visual placeholder shown to the user while the system is in the process of verifying their identity.

– Automatic Redirection: A security feature that ensures unauthorized users are immediately sent to the login screen to protect system data.

3.4 Business Value

– Security: By automatically validating sessions, the system prevents unauthorized access to sensitive ERP data.

–

User Experience: The personalized greeting provides a professional and welcoming interface, while the automatic redirection ensures users are always in the correct state to perform their work.

- Efficiency: The system handles authentication checks in the background, allowing for a seamless transition between pages without requiring manual user intervention.

BUSINESS REQUIREMENTS DOCUMENT

Products Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Products Sub Menu is a navigation component designed to help users easily switch between different product-related views within the Lumi ERP system. It functions as an accordion-style menu, providing a clear and organized way to access the main product lists. By default, the system highlights the "Products" section when a user first accesses the menu, ensuring they land on the primary product list immediately.

1.2 Step-by-Step Flow

1. Upon loading the Products section, the system automatically sets "Products" as the active view and displays the Products List Page.
2. The user is presented with an accordion menu containing two options: "Products" and "Service Products."
3. When the user clicks on "Products," the system updates the active state to "Products" and navigates the user to the Products List Page.
4. When the user clicks on "Service Products," the system updates the active state to "Service Products" and navigates the user to the Service Products List Page.

1.3 Key Concepts

- Accordion Menu: A vertical navigation style that organizes links into a compact, expandable list, keeping the interface clean.
- Active State: A visual indicator that highlights which menu item the user is currently viewing, helping them maintain context while navigating.
- Default State: The pre-selected setting that ensures the user sees the most relevant information (in this case, the main Products list) as soon as they arrive.
- Navigation Routing: The mechanism that directs the user to the correct page within the ERP system based on their menu selection.

1.4 Business Value

This feature improves the user experience by providing a predictable and intuitive way to navigate product categories. By standardizing the menu layout and ensuring a consistent "active" state, users can move between standard products and service products without losing their place. This reduces navigation friction and helps staff manage inventory and service offerings more efficiently within the ERP.

BUSINESS REQUIREMENTS DOCUMENT

Customers Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customers Menu is a sidebar navigation component designed for the Lumi ERP system. It provides a structured way for users to access key areas of the platform, specifically focusing on Customers, Vehicles, and Vouchers. The menu uses an "accordion" style, allowing users to expand or collapse specific sections to keep the interface clean and focused on the task at hand.

1.2 Step-by-Step Flow

1. Initial Load: When the user first accesses the system, the "Customers" menu is expanded by default, and the "Customers" category is highlighted as the active section.
2. Interaction: The user clicks on a main navigation item (Customers, Vehicles, or Vouchers).
3. State Update: The system updates the "active" highlight to the selected item and triggers the accordion logic.
4. Accordion Toggle: If the clicked section is closed, it expands to reveal specific sub-options (e.g., "Add New Customer" or "View All Vehicles"). If it is already open, clicking it again will collapse the sub-menu.
5. Navigation: Selecting a sub-option directs the user to the corresponding page within the ERP.

1.3 Key Concepts

- Accordion Menu: A design pattern where clicking a main header expands or collapses a list of sub-items, helping to save screen space.
- Active State: A visual indicator (highlighting) that shows the user which main category they are currently viewing.
- Navigation Item: The primary buttons in the sidebar that act as the entry points for the different modules (Customers, Vehicles, Vouchers).
- Sub-menu: The secondary list of specific actions or pages that appear once a main category is expanded.

1.4 Business Value

- Improved Usability: By organizing features into collapsible categories, users can navigate the ERP more intuitively without being overwhelmed by too many options at once.
- Efficiency: The default "Customers" view ensures that the most frequently used module is immediately accessible upon login, reducing the number of clicks required to start work.
- Consistency: The standardized accordion behavior across all menu items provides a predictable experience, making it easier for staff to learn and navigate the system quickly.

BUSINESS REQUIREMENTS DOCUMENT

Inventory Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Inventory Menu is the primary navigation sidebar for the Inventory module within the Lumi ERP system. It provides a clean, organized way for users to access different areas of the inventory system, such as Store management, Company details, and Reports. The menu uses an interactive "accordion" style, allowing users to expand or collapse specific sections to keep the interface uncluttered while navigating.

1.2 Step-by-Step Flow

1. Initial Load: When the Inventory module is opened, the "Store" section is selected by default and its sub-menu is automatically expanded.
2. Navigation Selection: Users can click on any of the main navigation items (Store, Company, or Reports).
3. State Update: Clicking an item highlights it as the "active" selection, providing visual feedback to the user about their current location.
4. Accordion Interaction:

– If the user clicks "Store" or "Company," the system toggles the visibility of the associated sub-menu (expanding it if closed, or collapsing it if open).
– A visual indicator (a chevron icon) updates automatically to show whether the section is currently expanded or collapsed.

5. Direct Navigation: For items without sub-menus (like "Reports"), clicking the item simply sets it as the active selection and triggers the navigation to that specific page.

1.3 Key Concepts

– Accordion Menu: A design pattern where clicking a header expands or hides a list of sub-options, helping to save screen space.
– Active State: A visual indicator that shows the user which menu item is currently selected or "in focus."
– Chevron Icon: A small arrow symbol used to indicate that a menu item can be expanded or collapsed.
– Sub-menu: A secondary list of options nested under a main navigation category.

1.4 Business Value

– Improved User Experience: By using an accordion layout, the menu prevents information overload, allowing users to focus only on the relevant sub-tasks they need at that moment.
– Consistent Navigation: Providing a clear, standardized menu structure ensures that users can move between inventory tasks quickly and intuitively, reducing the learning curve for the system.
– Efficient Workflow: The default selection of the "Store" menu ensures that the most frequently used features are immediately accessible upon entering the module, saving the user time.

BUSINESS REQUIREMENTS DOCUMENT

Suppliers Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Suppliers Menu is a navigation component designed to help users easily manage and access supplier-related tasks within the Lumi ERP system. It provides a clean, organized way to view supplier information by using an expandable menu structure, ensuring that key actions—such as viewing the supplier list or adding a new supplier—are always just a click away.

1.2 Step-by-Step Flow

1. Initial Load: When the user accesses the system, the "Supplier" menu is selected by default and is already expanded to show available options.
2. Interaction: The user clicks on the "Supplier" menu item.
3. Toggle Action: The system checks if the menu is currently expanded or collapsed. If it is expanded, clicking it will hide the sub-menu; if it is collapsed, clicking it will reveal the sub-menu.
4. Visual Feedback: The menu displays a small icon (a chevron) that changes direction to indicate whether the sub-menu is currently open or closed.
5. Navigation: Once the sub-menu is visible, the user can select specific tasks, such as viewing the "Supplier List" or choosing to "Create Supplier," which then directs the user to the corresponding page.

1.3 Key Concepts

- Accordion Menu: A design pattern where a menu item can be expanded or collapsed to show or hide additional sub-options, helping to keep the interface uncluttered.
- Active State: A visual indicator that highlights which section of the menu the user is currently interacting with or viewing.
- Sub-menu: A secondary list of specific actions or pages that are grouped under a primary category (in this case, "Supplier").
- Chevron Icon: A small arrow symbol used to visually signal that a menu item contains hidden content that can be toggled.

1.4 Business Value

This feature improves user efficiency by grouping all supplier-related activities into a single, intuitive location. By using an accordion-style navigation, the system reduces visual noise, allowing users to focus on the specific task at hand without being overwhelmed by too many options at once. This streamlined approach ensures a consistent and professional user experience across the ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

Sales Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Menu is the primary navigation component for the Sales module within the Lumi ERP system. It provides a clean, organized way for users to access different areas of the sales workflow—specifically Company, Store, and Service—using an accordion-style layout. By default, the "Store" section is expanded when the user first accesses the menu, ensuring the most common tasks are immediately visible.

1.2 Step-by-Step Flow

1. Initial Load: When the Sales module is opened, the "Store" menu is automatically selected and expanded to show its sub-options.
2. Navigation Selection: Users can click on any of the three main categories: "Company," "Store," or "Service."
3. State Update: Clicking a category highlights that item as the "active" selection.
4. Accordion Toggle: Each category acts as an accordion. Clicking a category toggles its specific sub-menu open or closed.
5. Visual Feedback: A chevron icon next to each category name updates automatically to indicate whether that section is currently expanded (pointing down) or collapsed (pointing right).

1.3 Key Concepts

- Accordion Menu: A design pattern where clicking a header expands or collapses a section of content, helping to keep the interface uncluttered.
- Active State: A visual indicator that highlights which menu item the user is currently interacting with or viewing.
- Chevron: A small arrow icon used to signal to the user that a menu item can be expanded or collapsed.
- Sub-menu: A secondary list of options nested under a main category, revealed only when the user chooses to expand that category.

1.4 Business Value

- Improved Usability: By using an accordion structure, the menu prevents information overload, allowing users to focus only on the specific sales area they are currently working in.
- Efficiency: Setting the "Store" menu as the default expanded view reduces the number of clicks required for the most frequent sales tasks.
- Consistency: The standardized navigation behavior across all three categories ensures that users can easily learn and navigate the system without confusion.

BUSINESS REQUIREMENTS DOCUMENT

Finance Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Finance Menu is a navigation component designed to help users easily access key financial tools within the ERP system. It provides a clean, organized list of primary categories—Invoices, Reports, and Settings—with a special "accordion" feature for the Invoices section to keep the interface uncluttered while providing quick access to detailed sub-tasks.

1.2 Step-by-Step Flow

1. Initial Load: When the Finance module is opened, the system defaults to the "Invoices" section. The sub-menu for invoices is automatically expanded to show options like "All Invoices," "Drafts," and "Pending Approval."
2. Navigation Selection: Users can click on any primary menu item (Invoices, Reports, or Settings). The system highlights the selected item to show the user their current location.
3. Accordion Interaction: When the user clicks on "Invoices," the system toggles the sub-menu. If it is open, it collapses; if it is closed, it expands.
4. Visual Feedback: A chevron icon next to the "Invoices" label rotates to indicate whether the sub-menu is currently expanded or collapsed.

1.3 Key Concepts

- Accordion Menu: A design pattern that allows a section of content to be expanded or collapsed, helping to save screen space by hiding sub-options until they are needed.
- Active State: A visual indicator (such as highlighting) that tells the user which menu item is currently selected or "active."
- Sub-menu: A secondary list of options nested under a primary category, providing more granular control (e.g., specific invoice statuses).

1.4 Business Value

- Improved Usability: By grouping related tasks under the "Invoices" accordion, users can find what they need without being overwhelmed by too many options at once.
- Efficiency: The default selection of "Invoices" ensures that users are immediately presented with the most frequently used financial tasks upon entering the module.
- Consistency: The clear visual feedback (highlighting and chevron icons) ensures users always know where they are in the system and how to access hidden navigation options, reducing training time and user error.

BUSINESS REQUIREMENTS DOCUMENT

Customer Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Sub Menu is a navigation component designed to help users easily switch between different customer categories within the Lumi ERP system. It functions as an accordion-style menu, providing a clean and organized way to access specific customer lists, such as Retail and Corporate customers.

1.2 Step-by-Step Flow

1. Initialization: When the Customer module is first accessed, the system automatically selects "Retail Customers" as the default active view.
2. User Interaction: The user selects a category (Retail or Corporate) from the sub-menu.
3. State Update: The system highlights the selected category to indicate it is currently active.
4. Navigation: The system directs the user to the corresponding page for the selected customer category.
5. URL Synchronization: If a user navigates to a customer page via a direct link or browser history, the menu automatically detects the current location and updates the highlighted tab to match the page being viewed.

1.3 Key Concepts

- Accordion Menu: A space-saving navigation style that allows users to expand or collapse sections to find specific information.
- Active State: A visual indicator (highlighting) that shows the user which section of the system they are currently viewing.
- Routing: The process of moving the user to a specific page within the software based on their menu selection.
- Synchronization: A background process that ensures the menu's visual state always matches the page currently displayed in the browser.

1.4 Business Value

- Improved Usability: By grouping customer types into a dedicated sub-menu, users can navigate the ERP system more intuitively without getting lost in complex menus.
- Consistency: The automatic synchronization between the URL and the menu ensures that the interface always reflects the user's current context, reducing confusion.
- Efficiency: Providing a clear, default starting point ("Retail Customers") streamlines the workflow for the most common user tasks, saving time during daily operations.

BUSINESS REQUIREMENTS DOCUMENT

Inventory Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Inventory Sub Menu is a navigation component designed to help users easily access various inventory-related tasks within the ERP system. It functions as an accordion-style menu, providing a clean and organized way to switch between different inventory management pages, such as stock orders, returns, and transfers.

1.2 Step-by-Step Flow

1. Initial Load: When a user first accesses the Inventory module, the system automatically selects "Stock Orders" as the active view and displays the Stock Order List page.
2. Menu Interaction: The user is presented with a list of inventory categories (e.g., Stock Returns, Stock Reservations, etc.).
3. Selection: When the user clicks on a specific menu item, the system updates the visual "active" state to highlight the user's choice.
4. Navigation: The system immediately directs the user to the corresponding page for that specific inventory task.

1.3 Key Concepts

- Accordion Menu: A space-saving navigation design that allows users to view and select from a list of related options within a single module.
- Active State: A visual indicator that highlights which menu item is currently selected, helping the user keep track of their location within the system.
- Default Routing: A safety feature that ensures the user is never presented with a blank screen; if they navigate to the main inventory area, the system automatically lands them on the most common task (Stock Orders).

1.4 Business Value

- Improved User Experience: By grouping all inventory-related tasks into one intuitive menu, users can switch between different workflows (like moving from checking stock reservations to processing a return) without getting lost.
- Increased Efficiency: The default landing page ensures that the most frequently used feature—Stock Orders—is immediately available, reducing the number of clicks required to start daily tasks.
- Consistency: Providing a standardized navigation structure across the Inventory module ensures that the system feels predictable and easy to learn for all staff members.

BUSINESS REQUIREMENTS DOCUMENT

Inventory Sub Menu (Company)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Inventory Sub-Menu is a navigation component designed for the company-level dashboard of the Lumi ERP system. It provides users with a quick and intuitive way to jump between key inventory management areas, ensuring that essential tasks like tracking orders and managing stock movements are easily accessible.

1.2 Step-by-Step Flow

1. The user views the Inventory sub-menu within the company dashboard.
2. The system checks the user's permissions to determine which menu items should be visible.
3. The user selects one of the available options:

* Purchase Orders: Navigates the user to the list of standard purchase orders.

* Purchase Returns: Navigates the user to the list of company purchase returns.

* Stock Outgoings: Navigates the user to the list of stock outgoing records.

4. Upon clicking an item, the system immediately redirects the user to the corresponding page.

1.3 Key Concepts

- Sub-Menu: A secondary navigation bar that helps organize specific tasks under a broader category (Inventory) to keep the interface clean.
- Permission-Based Access: A security feature that ensures users only see menu options for the specific modules they are authorized to use.
- Immediate Navigation: A design approach where clicking a menu item takes the user directly to their destination without requiring extra steps or form submissions.

1.4 Business Value

This feature improves operational efficiency by centralizing inventory-related workflows. By providing a clear, permission-aware navigation path, it reduces the time users spend searching for specific inventory pages and ensures that sensitive or restricted modules remain hidden from unauthorized personnel, maintaining both productivity and system security.

BUSINESS REQUIREMENTS DOCUMENT

Suppliers Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Suppliers Sub Menu is a navigation component designed to help users manage supplier-related tasks within the Lumi ERP system. It provides a clear, organized way to switch between viewing the existing list of suppliers and initiating the creation of a new supplier record. By default, the system directs users to the main supplier list, ensuring a consistent starting point for daily operations.

1.2 Step-by-Step Flow

1. Initial Load: When the user accesses the Suppliers module, the system automatically selects the "Suppliers" view as the default, displaying the list of existing suppliers.
2. Navigation Selection: The user interacts with the accordion-style menu to choose between "Suppliers" (the list view) or "New Supplier" (the creation form).
3. State Update: Upon clicking an option, the system highlights the selected item to provide visual feedback on the user's current location.
4. Page Transition: The system updates the main content area to show the requested page (either the list or the creation form).
5. Alternative Access: Users can also trigger the creation of a new supplier directly via a dedicated "New Supplier" button, which bypasses the menu to take them straight to the entry form.

1.3 Key Concepts

- Accordion Menu: A compact navigation style that organizes links into a collapsible list, keeping the interface clean.
- Active State: A visual indicator (highlighting) that shows the user which section of the module they are currently viewing.
- Default View: The pre-selected page that appears automatically when the module is first opened, reducing the number of clicks required to start work.
- Navigation Routing: The underlying mechanism that ensures the correct page content is displayed based on the user's selection.

1.4 Business Value

- Improved Efficiency: By providing a dedicated sub-menu, users can quickly toggle between viewing data and performing data entry without navigating back to the main dashboard.
- Enhanced Usability: The clear visual feedback (active state) and intuitive navigation structure reduce user error and help staff find the information they need faster.
-

Streamlined Workflow: Standardizing the entry point to the "Suppliers List" ensures that users always begin their tasks from a consistent, familiar screen.

BUSINESS REQUIREMENTS DOCUMENT

Sales Store Sub Menu

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Sales Store Sub Menu is a navigation component integrated into the ERP system's header. It provides users with quick, direct access to key sales-related modules, specifically designed to help staff manage store-based sales activities efficiently.

1.2 Step-by-Step Flow

1. The user accesses the ERP header and locates the Sales Store navigation menu.
2. The user selects "Sales List" to view the primary store sales records.
3. Alternatively, the user selects "Sales Ecommerce" to view sales data specifically related to online store transactions.
4. Upon clicking either option, the system immediately redirects the user to the corresponding page within the ERP.

1.3 Key Concepts

- Sales List: The central view for managing and reviewing standard store-based sales transactions.
- Sales Ecommerce: A specialized view dedicated to tracking and managing sales generated through online channels.
- Navigation Component: A user interface element that acts as a shortcut, allowing users to move between different areas of the software without needing to navigate through complex menus.

1.4 Business Value

This feature streamlines the user experience by reducing the number of clicks required to reach essential sales data. By separating standard store sales from ecommerce sales, the system allows staff to quickly switch between different operational workflows, ultimately improving productivity and ensuring that sales data is organized and easily accessible.

BUSINESS REQUIREMENTS DOCUMENT

Sales Company Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Company Sub Menu is a navigation component designed to help users quickly access key areas of the Sales module within the ERP system. It provides a centralized, easy-to-use list of links that allows staff to jump directly to essential sales-related tasks without navigating through complex menus.

1.2 Step-by-Step Flow

1. The user views the Sales Company Sub Menu, which displays three primary options: Sales Orders, Sales Order Returns, and Sales Deliveries.
2. When the user clicks "Sales Orders," the system immediately redirects them to the Sales Order list page.
3. When the user clicks "Sales Order Returns," the system redirects them to the list of processed returns.
4. When the user clicks "Sales Deliveries," the system redirects them to the list of outgoing sales deliveries.

1.3 Key Concepts

- Navigation Menu: A dedicated sidebar or header section that acts as a shortcut hub for specific functional areas.
- Redirect: The automatic action of moving the user from their current screen to a new page based on their selection.
- Interaction States: Visual cues (such as highlighting when hovering or selecting) that confirm to the user that a menu item is clickable and active.

1.4 Business Value

This feature improves operational efficiency by reducing the number of clicks required to perform daily sales tasks. By providing a clear, consistent navigation path, users can switch between managing orders, returns, and deliveries more fluidly, which minimizes time spent searching for screens and helps maintain focus on core sales activities.

BUSINESS REQUIREMENTS DOCUMENT

Sales Service Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Service Sub Menu is a navigation component integrated into the ERP system's header. Its primary purpose is to provide users with quick, direct access to service-related sales tasks. By organizing these options into a dedicated sub-menu, the system helps users navigate to specific service management areas without cluttering the main navigation bar.

1.2 Step-by-Step Flow

1. The user accesses the ERP header and locates the Sales Service navigation area.
2. The user selects the "Service Reservation" option from the sub-menu list.
3. Upon clicking, the system immediately redirects the user to the Service Reservation list page, where they can view and manage existing service bookings.

1.3 Key Concepts

- Sub-menu: A secondary navigation list that appears under a main category to provide more specific options.
- Service Reservation: A dedicated module within the ERP used to track and manage customer service requests and bookings.
- Navigation Redirect: The automated action of moving the user from their current screen to a specific destination page within the application.

1.4 Business Value

This feature improves operational efficiency by reducing the number of clicks required to reach critical service management tools. By centralizing service-related sales navigation, users can switch between tasks more fluidly, leading to a more intuitive workflow and faster processing of service-based sales orders.

BUSINESS REQUIREMENTS DOCUMENT

Setup Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Setup Menu is the primary navigation sidebar for the ERP system's configuration module. It is designed to help users easily locate and manage administrative settings by grouping related tasks into collapsible categories. By default, the system opens with the "Company" section expanded, ensuring that the most common configuration tasks are immediately accessible upon login.

1.2 Step-by-Step Flow

1. Initial Load: When the user accesses the Setup module, the "Company" menu is expanded by default, and the "Company Profile" page is set as the active view.
2. Category Selection: The menu is organized into three main categories: Company, Areas, and Finances. Users can click on any of these category headers to reveal or hide the specific tasks contained within them.
3. Accordion Interaction: Clicking a category header acts as a toggle (an accordion style). If a category is closed, clicking it opens the list; if it is already open, clicking it closes the list.
4. Task Selection: Once a category is expanded, the user can click on a specific sub-item (e.g., "Tax Settings" or "Provinces").
5. State Update: Upon selecting a sub-item, the system highlights that item as "active" to provide visual feedback, and the main content area updates to display the corresponding page.

1.3 Key Concepts

- Accordion Menu: A navigation style where clicking a main heading expands or collapses a list of sub-items, helping to keep the interface clean and uncluttered.
- Active State: A visual indicator (highlighting) that shows the user which specific page or setting they are currently viewing.
- Category Grouping: The logical organization of settings into related buckets (Company, Areas, Finances) to improve findability and reduce cognitive load.

1.4 Business Value

- Improved User Experience: By using an accordion-style menu, the interface remains organized and prevents the user from being overwhelmed by too many options at once.
- Efficiency: Users can quickly navigate between related administrative tasks without needing to return to a main dashboard, saving time during system configuration.
- Consistency: The standardized navigation structure ensures that users can intuitively find settings across different modules, reducing the learning curve for new staff.

BUSINESS REQUIREMENTS DOCUMENT

Finance Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Finance Sub Menu is a navigation component designed to help users easily move between key areas of the Finance module within the ERP system. It uses an "accordion" style layout, which keeps the interface clean by organizing related tasks into collapsible groups. Upon loading the Finance module, the system defaults to the "Inventories" section to ensure users have immediate access to their most common tasks.

1.2 Step-by-Step Flow

1. Initial Load: When the Finance module is opened, the menu automatically highlights "Inventories" as the active tab and displays its sub-options.
2. Navigation Selection: Users can click on any of the main menu items (Dashboard, Inventories, Accounts, or Reports) to switch their view.
3. State Update: As the user clicks a new item, the system updates the active tab to reflect the current selection.
4. Expanding/Collapsing: If the user clicks on "Inventories," the menu will toggle the visibility of the sub-navigation list, allowing the user to show or hide specific inventory tasks (Stock Levels, Valuation, and Adjustments) as needed.

1.3 Key Concepts

- Accordion Menu: A vertical list of items that can be expanded or collapsed to show or hide detailed information, helping to save screen space.
- Active Tab State: A visual indicator that shows the user which section of the system they are currently viewing.
- Nested Dropdown: A secondary list of links that appears underneath a main menu item, providing quick access to specific sub-tasks without cluttering the main navigation.

1.4 Business Value

- Improved Efficiency: By defaulting to the "Inventories" section, the system reduces the number of clicks required for users to reach their most frequent workspace.
- Better Organization: The accordion structure keeps the interface tidy, allowing users to focus on the specific financial tasks they need while hiding irrelevant options.
- Enhanced User Experience: The clear visual feedback (highlighting the active tab) ensures users always know where they are within the application, reducing navigation errors and training time.

BUSINESS REQUIREMENTS DOCUMENT

Setup Sub Menu (Company)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Company" sub-menu is a new navigation component designed to help users easily manage their organizational information within the Lumi ERP system. It functions as an accordion-style menu, providing a clean and organized way to switch between core company management tasks. By default, the system directs users to the Company Data view, ensuring they land on the most relevant information immediately upon accessing this section.

1.2 Step-by-Step Flow

1. Initial Load: When a user accesses the "Company" section, the sub-menu defaults to the "Company Data" view, which is automatically highlighted to show it is the active page.
2. Selecting Company Data: If the user is on a different screen and clicks "Company Data," the system updates the menu highlight and navigates the user to the Company List page.
3. Selecting Company Settings: If the user clicks "Company Settings," the system updates the menu highlight to reflect this choice and navigates the user to the Company Settings page.
4. Visual Feedback: As the user switches between these options, the menu provides clear visual cues (such as bold text and a side border) to indicate which section is currently active.

1.3 Key Concepts

- Accordion Menu: A vertical navigation list that keeps related links grouped together, helping to save screen space while keeping options accessible.
- Active State: A visual indicator that tells the user exactly which page or section they are currently viewing.
- Navigation Routing: The behind-the-scenes process that ensures clicking a menu item instantly loads the correct page without requiring a full page refresh.

1.4 Business Value

This feature improves the user experience by providing a predictable and intuitive way to navigate the ERP system. By grouping "Company Data" and "Company Settings" together, users can switch between operational tasks and configuration settings with a single click. This reduces navigation time and helps users maintain focus on their work by providing clear, persistent visual feedback on their current location within the application.

BUSINESS REQUIREMENTS DOCUMENT

Setup Sub Menu (Finances)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Finances Sub-Menu" is a new navigation component designed to help users easily manage financial settings within the ERP system. It acts as a dedicated sidebar or accordion menu located under the main "Setup" area, allowing users to quickly switch between different financial configuration pages without leaving the setup environment.

1.2 Step-by-Step Flow

1. Initialization: When a user accesses the Setup area, the Finances sub-menu appears, with the "Finances" option selected by default.
2. User Selection: The user clicks on a specific item within the sub-menu, such as "Payment Types."
3. State Update: The system highlights the selected item to show the user exactly where they are in the navigation.
4. Navigation: The system automatically loads the corresponding page (e.g., the Payment Types list) so the user can begin their work.

1.3 Key Concepts

- Accordion Menu: A compact navigation style that organizes links into a collapsible list, keeping the interface clean and uncluttered.
- Active Tab State: A visual indicator that tells the user which section of the menu is currently open or selected.
- Navigation Routing: The behind-the-scenes process that ensures clicking a menu item instantly takes the user to the correct page in the system.

1.4 Business Value

- Improved Usability: By grouping financial settings into a single, intuitive menu, users can find the tools they need faster, reducing the time spent searching through the system.
- Consistent Experience: The standardized navigation structure ensures that moving between different financial settings feels predictable and professional.
- Reduced Complexity: Providing a clear path to specific tasks, such as managing payment types, helps streamline administrative workflows and minimizes user error.

BUSINESS REQUIREMENTS DOCUMENT

Sales Areas Sub Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Areas Sub Menu is a navigation component designed to help users manage geographical sales data within the ERP system. It functions as an accordion-style menu located under the main Setup section, allowing users to quickly switch between viewing lists of Provinces and Districts. By default, the system opens to the Provinces view to ensure users land on the most relevant information immediately upon accessing this area.

1.2 Step-by-Step Flow

1. Initialization: When the user accesses the Sales Areas section, the system automatically selects "Provinces" as the active view and displays the Province List Page.
2. User Selection: The user interacts with the navigation menu to choose between "Provinces" or "Districts."
3. State Update: The system updates the menu to highlight the user's current selection.
4. Page Transition: Based on the selection, the system triggers a view change to display the corresponding data list (either the Province List or the District List).

1.3 Key Concepts

- Accordion Menu: A space-saving navigation style that allows users to expand or collapse sections, keeping the interface clean and organized.
- Active State: A visual indicator that shows the user which section of the menu they are currently viewing.
- Default View: The pre-selected page that appears automatically when the user first opens the menu, reducing the number of clicks required to start a task.

1.4 Business Value

This feature improves the user experience by providing a clear, intuitive way to navigate complex geographical data. By grouping Provinces and Districts into a dedicated sub-menu, we reduce screen clutter and help staff locate and manage sales territories more efficiently. The use of a default landing page ensures that the most common administrative tasks are accessible with minimal effort.

BUSINESS REQUIREMENTS DOCUMENT

Finance Sub Menu - Inventories

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Finance Inventories Sub-Menu is a navigation component designed to help users easily access key inventory-related tasks within the Lumi ERP system. It functions as an accordion-style menu, providing a clean and organized way to switch between different financial inventory views, starting with Sales Invoices.

1.2 Step-by-Step Flow

1. The user accesses the Finance section of the ERP system.
2. The system displays the "Finance - Inventories" sub-menu as an accordion list.
3. The user selects a specific navigation item (e.g., "Sales Invoices") from the list.
4. The system updates the interface to highlight the selected item as the "active" tab.
5. The system automatically redirects the user to the corresponding page for that inventory task.

1.3 Key Concepts

- Accordion Menu: A vertical list of items that can be expanded or collapsed to keep the interface organized and uncluttered.
- Active Tab: A visual indicator that shows the user which section of the inventory module they are currently viewing.
- Navigation Routing: The behind-the-scenes process that ensures clicking a menu item takes the user to the correct, specific page within the ERP.

1.4 Business Value

This feature improves user efficiency by centralizing inventory-related financial tasks in one predictable location. By providing a clear, consistent navigation structure, it reduces the time users spend searching for specific documents like Sales Invoices, ultimately streamlining the financial workflow and reducing navigation errors.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get All Products" feature provides a secure way for authorized users to retrieve a comprehensive list of products stored in the Lumi ERP system. To ensure the system remains fast and responsive, the feature uses pagination, allowing users to request specific "pages" of data rather than loading the entire product catalog at once.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is authorized to access the product data. If the user is not logged in or their credentials are invalid, the request is denied.
2. Parameter Validation: The system checks the requested page number and the number of items per page (limit). If these numbers are invalid (e.g., negative numbers or exceeding the maximum allowed limit), the system returns an error.
3. Data Retrieval: The system calculates which specific products belong on the requested page and fetches them from the database, along with the total count of all products available.
4. Response Delivery: The system returns the requested list of products, including key details like the product name, SKU, price, stock levels, and creation date, along with metadata about the current page and total product count.

1.3 Key Concepts

- Pagination: A method of breaking a large list of items into smaller, manageable chunks (pages) to improve performance and readability.
- Authentication: A security step that ensures only verified users can access sensitive business data.
- Metadata: Additional information provided with the product list, such as the total number of products in the database, which helps the user interface display navigation controls (like "Page 1 of 10").
- Query Parameters: Specific settings included in the request (like "page" or "limit") that allow the user to customize the data they receive.

1.4 Business Value

This feature enables seamless integration between the Lumi ERP and other business tools or dashboards. By providing a paginated list, the system ensures that users can efficiently browse large inventories without experiencing slow load times. Furthermore, the inclusion of total count metadata allows for a better user experience, as it enables the front-end application to accurately display navigation tools, helping staff manage inventory more effectively.

2. Data

2.1 Overview

The "Get All Products" feature provides a reliable way for the Lumi ERP system to retrieve a comprehensive list of products currently stored in the database. To ensure the system remains fast and responsive even as the product catalog grows, this feature uses "pagination," which breaks the list into smaller, manageable chunks. It also provides helpful summary information, such as the total number of products available, to assist with navigation.

2.2 Step-by-Step Flow

1. Request: The system receives a request for the product list, including the specific page number and the number of items to display per page.
2. Calculation: The system calculates which specific set of products to retrieve based on the requested page and limit.
3. Counting: The system counts the total number of products in the database to provide context for the user.
4. Retrieval: The system fetches the requested batch of products, sorted by the most recently added items first.
5. Response: The system returns the list of products along with metadata (the current page, the limit used, and the total count of all products).
6. Error Handling: If the database is unreachable, the system reports a server error. If no products are found, the system returns an empty list rather than an error, confirming the request was successful but no data exists.

2.3 Key Concepts

- Pagination: A method of dividing a large list of data into smaller pages to improve performance and user experience.
- Metadata: Additional information provided with the product list (such as total count and page numbers) that helps the application display the data correctly.
- Sorting: The products are automatically organized by their creation date, ensuring the newest items appear at the top of the list.
- Empty State: A standard response indicating that the request was processed successfully, even if the database currently contains no products.

2.4 Business Value

This feature is essential for inventory management and reporting within the Lumi ERP. By implementing pagination, we ensure that the application remains performant and stable, regardless of how many thousands of products are

added to the system. Providing clear metadata allows the user interface to accurately display navigation controls (like "Next" or "Previous" buttons), making it easier for staff to browse and manage the product catalog efficiently.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products?utf8= &q[attribute_predicate]=value&...&page_rows=

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Product Search API allows users to retrieve a filtered list of products from the Lumi ERP system. It provides a flexible way to search the catalog by combining various criteria—such as product names, codes, brands, or custom information fields—and allows users to control how many results are displayed at once.

1.2 Step-by-Step Flow

1. Security Check: The system first verifies that the user is logged in and has the necessary permissions to view the product list.
2. Parameter Processing: The system collects the search criteria (filters) and the requested number of results per page. If no specific page size is provided, it defaults to 20 items.
3. Validation: The system checks that any specific IDs provided for filtering (such as Brand, Product Type, or Tax categories) actually exist in the database. If an ID is invalid, the request is rejected.
4. Search Execution: The system builds a dynamic search query based on the provided filters. It looks for matches across the specified product attributes and applies any requested sorting.
5. Data Retrieval: The system fetches the matching products from the database and returns them to the user.

1.3 Key Concepts

- Filtering: The ability to narrow down search results using specific attributes like SKU, name, brand, or custom information fields.
- Pagination: A feature that limits the number of results returned in a single request, helping to keep the system fast and the data easy to manage.
- Validation: A safety step that ensures the search criteria are not only formatted correctly but also refer to valid data existing within the ERP.
- Authorization: A security measure ensuring that only users with the appropriate access rights can perform product searches.

1.4 Business Value

This feature empowers users to quickly locate specific items within a large product catalog without manual browsing. By supporting a wide range of search filters, it improves operational efficiency for staff who need to manage inventory, update product details, or assist customers. The inclusion of pagination ensures that the application remains responsive even as the product catalog grows.

2. Data

2.1 Overview

The Product Search API allows users to retrieve a filtered list of products from the Lumi ERP system. It provides a flexible way to search the catalog by combining various criteria—such as product names, codes, brands, types, and tags—into a single request. The feature is designed to be efficient, allowing users to specify how many results they want to see at once and how those results should be sorted.

2.2 Step-by-Step Flow

1. Request Submission: The user sends a request to the system with specific search criteria (e.g., searching for a specific brand or a product name containing certain text).
2. Validation: The system checks if the provided search criteria are valid. If the user references a specific ID (like a Brand or Tax ID) that does not exist in the system, the request is rejected.
3. Filtering: The system applies the requested filters to the product database. This includes:

* Text matching: Finding products where the name, SKU, or info fields contain the provided text.

* Exact matching: Finding products that match specific IDs for brands, types, or tax categories.

* Tag filtering: Finding products associated with specific tags.

4. Sorting and Pagination: The system organizes the results based on the user's preferred order (e.g., by name) and limits the number of items returned to match the requested page size.
5. Response: The system returns the matching list of products. If the request is invalid, unauthorized, or encounters an error, the system provides an appropriate status code to explain the issue.

2.3 Key Concepts

- Filters: The criteria used to narrow down the product list, such as searching by name, SKU, or category.
- Exact Match: A search requirement where the system looks for an item that matches a specific ID exactly, rather than just containing a piece of text.
- Text Containment: A search method that returns results if the search term is found anywhere within a specific field (e.g., searching "Blue" would return "Blue Shirt" and "Dark Blue Pants").
- Pagination: A method to control the volume of data returned by limiting the number of products shown per request, which helps keep the system fast and responsive.
- Sorting: The ability to arrange the final list of products in a specific order, such as alphabetically by name.

2.4 Business Value

This feature empowers users to quickly locate specific items within a large product catalog without needing to manually browse through every entry. By supporting complex, multi-parameter searches, it reduces the time spent

on administrative tasks and ensures that sales, inventory, and procurement teams can access the exact product data they need to make informed business decisions.

GET /api/products?status=:status

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. LOGIC

1.1 Overview

The Product API allows authorized users to retrieve a list of products from the Lumi ERP database. This feature is designed to be flexible, enabling users to search for products based on specific criteria—such as their status (active or inactive), brand, type, or tags—while also supporting pagination to ensure the system remains performant when handling large amounts of data.

1.2 Step-by-Step Flow

1. Security Check: The system first verifies that the user is logged in and possesses the necessary permissions to view the product list.
2. Filter Validation: The system checks the search criteria provided in the request to ensure they are formatted correctly and contain valid data types.
3. Reference Verification: If the user is filtering by specific categories like "Brand" or "Product Type," the system confirms that these items actually exist in the database before proceeding.
4. Data Retrieval: The system applies all valid filters (such as name, SKU, or tags) to the database query.
5. Pagination: The system organizes the results into pages based on the requested page number and the number of rows per page.
6. Response: The system returns the filtered list of products to the user, or provides an appropriate error message if the request could not be completed.

1.3 Key Concepts

- Filtering: The ability to narrow down the product list using specific attributes like status, SKU, name, brand, or product type.
- Pagination: A method of breaking down a large list of results into smaller, manageable chunks (pages) to improve system speed and user experience.
- Authorization: The security process that ensures only users with the correct access rights can view product information.
- Validation: The process of checking that the information sent in a request is accurate and follows the required format before the system attempts to process it.

1.4 Business Value

This feature provides a robust and efficient way for users to manage their inventory data. By allowing precise filtering and pagination, it enables staff to quickly locate specific products without overwhelming the system.

Furthermore, the built-in security and validation checks ensure that sensitive product data remains protected and that the system maintains high reliability and data integrity.

2. DATA

2.1 Overview

This feature provides a way to retrieve a list of products from the Lumi ERP system. Users can filter the product list by their current status (active or inactive) and apply additional criteria to narrow down the results. The system also supports pagination, allowing users to request specific "pages" of data to keep the information manageable.

2.2 Step-by-Step Flow

1. Request Initiation: The user sends a request to view products, specifying whether they want "active" or "inactive" items.
2. Validation: The system checks if any provided identifiers (such as Brand ID, Type ID, or Tag IDs) actually exist in the database. If an ID is provided that does not exist, the request is rejected.
3. Filtering: The system applies the status filter and any optional search criteria provided by the user, such as partial matches for product names, SKUs, or specific category IDs.
4. Pagination: The system calculates which specific subset of data to return based on the requested page number and the number of rows per page.
5. Data Retrieval: The system gathers the matching records and returns them to the user.

2.3 Key Concepts

- Status Filter: A mandatory requirement that ensures the user only sees products that are currently marked as either "active" or "inactive."
- Optional Search Criteria: Flexible filters that allow users to find products by partial names, codes, or specific attributes like brand, type, or tags.
- Pagination: A method of breaking a large list of results into smaller, manageable chunks (pages) to improve performance and readability.
- Reference Validation: A safety check that ensures any specific IDs provided in the search (like a Brand ID) are valid and exist in the system before attempting to search for them.

2.4 Business Value

This feature enables efficient product management by allowing staff to quickly locate specific items without having to browse the entire database. By supporting both active and inactive status filtering, it helps teams maintain clean

inventory records and easily audit discontinued or archived products. The inclusion of pagination ensures that the system remains fast and responsive, even as the product catalog grows over time.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve detailed information about a specific product within the Lumi ERP system. By providing a unique product identifier, users can instantly access a standardized summary of that product, including its name, SKU, pricing, description, and relevant timestamps.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided product ID is formatted correctly. If the format is incorrect, the request is rejected.
2. Authentication: The system verifies that the user has the necessary permissions to access the product data. If the user is not logged in or lacks valid credentials, the request is denied.
3. Data Retrieval: The system searches the database for a product matching the provided ID.
4. Verification: If no product is found in the database for that specific ID, the system informs the user that the product does not exist.
5. Data Delivery: If the product is found, the system returns the full product details in a consistent, structured format.
6. Error Handling: If an unexpected technical issue occurs during the process, the system logs the error and notifies the user that a server-side problem has occurred.

1.3 Key Concepts

- Product ID: A unique digital fingerprint assigned to every product, ensuring the system retrieves the exact item requested.
- Authentication: A security gate that ensures only authorized users can view sensitive product information.
- Standardized Schema: A consistent "template" for product data, ensuring that every product returned by the system follows the same structure (e.g., name, price, and description are always in the same format).
- Error Handling: Built-in safeguards that provide clear feedback if a request fails, such as identifying if an ID is invalid or if the system is experiencing temporary technical difficulties.

1.4 Business Value

This feature serves as a foundational building block for the Lumi ERP, enabling seamless integration between the product database and other parts of the business. By providing a reliable and standardized way to fetch product details, it ensures that sales, inventory, and reporting tools always have access to accurate, up-to-date information, reducing manual data entry and minimizing errors in product management.

2. Data

2.1 Overview

This feature provides a way for external systems to retrieve detailed information about a specific product within the Lumi ERP system. By using a unique product identifier, users can request a standardized data package containing all relevant product attributes, such as name, pricing, and stock-keeping unit (SKU) information.

2.2 Step-by-Step Flow

1. Validation: The system first checks that the provided product identifier is formatted correctly. If the format is invalid, the request is rejected.
2. Database Lookup: The system searches the product database using the provided identifier.
3. Verification: If no product is found matching that identifier, the system reports that the requested resource does not exist.
4. Data Transformation: If the product is found, the system converts the raw database information into a clean, standardized format.
5. Delivery: The final, formatted product details are returned to the requester.

2.3 Key Concepts

- Product Identifier: A unique code used to pinpoint a specific item in the system.
- Standardized Schema: A consistent structure for data, ensuring that every product request returns information in the exact same format, making it easier for other systems to read.
- Validation: A security and quality check performed at the start to ensure the request is formatted correctly before processing begins.
- Error Handling: Built-in responses for common issues, such as requesting a product that doesn't exist or providing an incorrectly formatted ID.

2.4 Business Value

This feature enables seamless integration between the Lumi ERP and other business tools. By providing a reliable, standardized way to fetch product data, it ensures that sales, inventory, and e-commerce platforms always have access to accurate and up-to-date product information, reducing manual data entry and minimizing errors across the organization.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/products

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way to add new products to the Lumi ERP system. By sending product details—such as the unique identifier (SKU), name, description, and price—to this endpoint, the system automatically registers the item, assigns it a unique ID, and records the creation time. The process includes built-in safeguards to ensure that only authorized users can add products and that no duplicate items are created.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the person attempting to add a product is currently signed in. If not, the request is rejected.
2. Validation: The system checks the provided information to ensure all mandatory fields (SKU, name, and price) are included. If any are missing, the request is rejected.
3. Duplicate Check: The system searches the database to ensure no other product already uses the same SKU. If a match is found, the request is rejected to prevent duplicates.
4. Record Creation: If all checks pass, the system generates a unique ID and timestamps for the product, saves the information to the database, and confirms the successful creation of the record.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique code used to identify a specific product in your inventory.
- Authentication: The security step that confirms the user has permission to perform the action.
- Validation: The process of ensuring the data provided is complete and formatted correctly before it is saved.
- Duplicate Prevention: A safety mechanism that stops the system from creating two different products with the same unique identifier.

1.4 Business Value

This feature streamlines inventory management by providing a reliable, automated way to ingest product data into the Lumi ERP. By enforcing data quality (via validation) and preventing errors (via duplicate checks), it ensures that your product catalog remains accurate and organized. Furthermore, the automated handling of IDs and timestamps reduces manual data entry, saving time and minimizing the risk of human error.

2. Data

2.1 Overview

The "Create Product" feature allows authorized users to add new items to the Lumi ERP system. When a user submits product details, the system automatically handles the assignment of unique identifiers and timestamps, ensuring that the data is consistent and accurate without requiring manual input for these fields.

2.2 Step-by-Step Flow

1. Validation: The system checks the incoming request to ensure that essential information, specifically the SKU (Stock Keeping Unit) and the product name, is provided. If these are missing, the request is rejected.
2. Uniqueness Check: The system searches the database to verify that the provided SKU is not already in use. If a match is found, the system prevents the creation of a duplicate record.
3. Data Preparation: If the validation and uniqueness checks pass, the system automatically generates a unique ID for the product and records the current date and time for both the creation and update timestamps.
4. Persistence: The new product information is saved into the database.
5. Confirmation: Upon successful saving, the system returns the complete product record to the user to confirm the action was successful.

2.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track individual products in the inventory.
- Validation: The process of ensuring that the data submitted by the user meets the minimum requirements before the system attempts to process it.
- Uniqueness Constraint: A safeguard that prevents the system from creating two different products with the same SKU, which helps maintain data integrity.
- Automated Metadata: Information such as unique IDs and timestamps that the system generates internally, removing the burden from the user and ensuring consistency.

2.4 Business Value

This feature streamlines inventory management by providing a reliable and standardized way to add new products to the ERP. By automating ID generation and timestamping, it reduces the risk of human error. Furthermore, the built-in validation and duplicate-checking mechanisms ensure that the product catalog remains clean, organized, and free of conflicting data, which is essential for accurate reporting and sales operations.

BUSINESS REQUIREMENTS DOCUMENT

PUT /api/products/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to perform a full update on an existing product record within the Lumi ERP system. When a user submits changes—such as updating the product name, price, or stock levels—the system ensures the request is secure, validates that the data is accurate, and automatically logs these changes for auditing purposes.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and possesses the necessary permissions to modify product information.
2. Record Retrieval: The system locates the specific product in the database using the provided ID. If the product does not exist, the process stops and notifies the user.
3. Data Validation: The system checks if the user is trying to change the product's SKU. If they are, it confirms that the new SKU is not already being used by another product to prevent duplicates.
4. Change Tracking: The system compares the new information against the existing data to identify exactly which fields are being modified.
5. Update and Audit: The system saves the updated product details and simultaneously records each specific change in an audit log. If any part of this process fails, the system cancels the entire operation to ensure data consistency.
6. Confirmation: Once successfully saved, the system returns the updated product information to the user.

1.3 Key Concepts

- Authentication & Authorization: Security measures that confirm who the user is and ensure they have the specific rights required to edit product data.
- SKU Uniqueness: A validation rule that prevents two different products from sharing the same Stock Keeping Unit (SKU) identifier.
- Audit Log: A permanent record of changes that tracks what was modified, what the value was before the change, and what it was changed to.
- Transaction: A safety mechanism that ensures the product update and the audit log entry are treated as a single action; if one fails, both are rolled back to prevent data errors.

1.4 Business Value

This feature provides a reliable and secure way to maintain product data integrity. By enforcing strict validation and maintaining a detailed audit trail, the business can ensure that product information remains accurate and that there is full accountability for any changes made to the inventory catalog.

2. Data

2.1 Overview

This feature enables the full update of product information within the Lumi ERP system. When a user submits changes to a product, the system ensures that all product details are updated accurately. Additionally, the system includes a built-in security measure that automatically tracks and logs any changes made to a product's "active" status, providing a clear history of when a product was enabled or disabled.

2.2 Step-by-Step Flow

1. Locate Product: The system identifies the specific product in the database using the unique ID provided in the request.
2. Initiate Update: The system begins a secure transaction to ensure that the product update and any necessary audit logging happen together as a single, reliable action.
3. Apply Changes: The system updates the product’s core information (such as name, description, price, and stock levels) and records the current time of the update.
4. Check Status Toggle: The system compares the product's previous "active" status with the new status.
5. Log Changes (if applicable): If the "active" status has changed, the system creates an entry in the audit log detailing the previous status, the new status, and the time the change occurred.
6. Finalize: The system saves all changes permanently. If any errors occur during this process, the system will report the issue (such as invalid data or a server error) to ensure the database remains consistent.

2.3 Key Concepts

- Full Update: A process where the system replaces the existing product information with the new data provided in the request.
- Transaction: A safety mechanism that ensures all parts of an update (the product change and the audit log) are completed successfully together; if one part fails, the entire update is canceled to prevent data errors.
- Audit Log: A secure record-keeping feature that tracks specific, important changes to product data for accountability and historical reference.
- Constraint Violation: A scenario where the submitted data does not meet the system's rules (e.g., missing required information or invalid formats), resulting in a request rejection.

2.4 Business Value

This feature ensures data integrity by providing a reliable way to manage product catalogs while maintaining a transparent history of status changes. By automatically logging when a product is toggled between active and inactive, the business gains better visibility into inventory management and operational changes, reducing the risk of unauthorized or accidental status updates going unnoticed.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/vouchers/flexible

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Flexible Voucher" feature allows authorized users to create new, customizable vouchers within the Lumi ERP system. By providing a unique identifier (SKU), a name, a monetary value, and a currency, users can generate vouchers that are immediately stored and ready for use. The system automatically handles the assignment of unique IDs and timestamps to ensure data consistency and auditability.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and possesses the necessary permissions to create vouchers.
2. Data Validation: The system checks the incoming information to ensure all required fields (SKU, name, value, and currency) are present and formatted correctly.
3. Uniqueness Verification: The system checks the database to ensure the provided SKU is not already in use, preventing duplicate entries.
4. Record Creation: If all checks pass, the system generates a unique ID and timestamps for the voucher, saves it to the database, and confirms the creation by returning the full voucher details.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique code used to identify a specific type of voucher, ensuring that each voucher can be tracked individually.
- Authentication: The process of verifying the identity of the user to ensure they are authorized to access the system.
- Validation: A safety check performed by the system to ensure that the data provided by the user meets all business requirements before it is saved.
- Conflict Handling: A protective measure that prevents the system from saving a new voucher if its unique identifier already exists, avoiding data corruption.

1.4 Business Value

This feature provides the flexibility needed to manage diverse promotional or payment instruments within the ERP. By automating the generation of IDs and timestamps, it reduces manual data entry errors and ensures that every voucher is accurately tracked from the moment it is created. The built-in validation and security checks ensure that only authorized personnel can create vouchers, maintaining the integrity of the company's financial and inventory data.

2. Data

2.1 Overview

The "Create Flexible Voucher" feature allows authorized users to add new voucher types to the Lumi ERP system. This tool is designed to be flexible, enabling the business to define unique vouchers by providing a specific stock-keeping unit (SKU), a name, and a monetary value. The system automatically handles administrative details like unique identification and timestamps, ensuring data consistency and preventing duplicate entries.

2.2 Step-by-Step Flow

1. Submission: The user submits a request containing the voucher details (SKU, name, description, value, and currency).
2. Validation: The system checks that all mandatory fields (SKU, name, and value) are present and correctly formatted. If information is missing, the request is rejected.
3. Conflict Check: The system verifies that the provided SKU is not already in use by another voucher. If a duplicate is found, the request is rejected to maintain data integrity.
4. System Enrichment: Once validated, the system automatically assigns a unique identifier to the voucher and records the exact date and time of creation.
5. Confirmation: The new voucher is saved to the database, and the system returns a success confirmation to the user.

2.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track a specific type of voucher; no two vouchers can share the same SKU.
- Validation: A safety check performed by the system to ensure that all required information is provided before processing begins.
- Conflict Handling: A protective measure that prevents the system from creating duplicate records if a user attempts to add a voucher with an existing SKU.
- System-Generated Fields: Data points, such as unique IDs and creation timestamps, that the system creates automatically so the user does not have to manage them manually.

2.4 Business Value

This feature streamlines the voucher management process by automating the administrative overhead of record-keeping. By enforcing strict validation and preventing duplicate SKUs, the system ensures that financial and inventory data remains accurate and reliable. This allows the business to quickly and confidently scale its voucher offerings without the risk of data entry errors or conflicting records.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id/warehouse_stock_history

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to view the complete stock movement history for a specific product within the Lumi ERP system. By providing a detailed log of every transaction—such as stock additions, removals, or adjustments—this tool offers full visibility into how a product's inventory levels have changed over time across different warehouses.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and possesses the necessary permissions to view sensitive stock history data.
2. Product Verification: The system checks if the requested product exists in the database. If the product ID is invalid, the system notifies the user that the product could not be found.
3. Data Retrieval: If the user is authorized and the product exists, the system gathers all recorded stock transactions associated with that product.
4. Display Results: The system presents the transaction history, organized from the most recent activity to the oldest, including details like the warehouse location, the amount changed, and the type of transaction.
5. Error Handling: If an unexpected issue occurs during the process, the system logs the event for internal review and informs the user that a server error has occurred.

1.3 Key Concepts

- Stock Transaction: A specific event that alters the inventory count of a product, such as a shipment arrival, a customer order, or an internal stock transfer.
- Authentication: The process of confirming the user's identity to ensure only verified staff can access the system.
- Authorization: The process of checking if a verified user has the specific "view stock history" permission required to see this data.
- Transaction History: A chronological record of all past movements for a product, which helps in auditing and inventory reconciliation.

1.4 Business Value

This feature provides essential transparency for inventory management. By tracking the "who, what, and where" of stock changes, businesses can:

- Improve Accountability: Easily trace discrepancies in inventory levels back to specific transactions.
-

Enhance Decision Making: Analyze historical trends to better forecast future stock needs.

- Streamline Auditing: Quickly generate reports for compliance and financial reviews without manual data compilation.

2. Data

2.1 Overview

This feature allows authorized users to view the complete transaction history for a specific product within the warehouse. By retrieving a chronological log of stock changes, users can track how and when a product's inventory levels have fluctuated, ensuring better visibility and accountability for stock movements.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the person requesting the information is logged in and has a valid session.
2. Product Verification: The system checks if the requested product exists in the database. If the product cannot be found, the request is stopped.
3. Permission Check: The system confirms that the user has the specific authorization required to view stock history for that product.
4. Data Retrieval: If all checks pass, the system gathers all recorded stock transactions for the product.
5. Display: The system presents the transaction history, automatically sorted so that the most recent changes appear at the top of the list.

2.3 Key Concepts

- Stock Transaction: A record of a specific event that changed the inventory level of a product, such as a shipment arrival, a customer order, or an internal adjustment.
- Authentication: The process of confirming the identity of the user to ensure they are a recognized member of the system.
- Authorization: The process of verifying that a confirmed user has the specific rights or "permissions" to access sensitive inventory data.
- Chronological Sorting: The method of organizing data by time, ensuring the user sees the latest activity first.

2.4 Business Value

- Improved Inventory Accuracy: By providing a clear audit trail of every stock change, teams can easily identify discrepancies and understand the "why" behind current inventory levels.
-

Enhanced Security: Strict authentication and permission checks ensure that sensitive warehouse data is only accessible to authorized personnel.

- Operational Transparency: Providing a detailed history of stock movements helps managers make informed decisions regarding restocking, demand planning, and identifying potential supply chain bottlenecks.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id/warehouse-stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to view exactly how much of a specific product is stored across your various warehouses. Instead of just showing a simple count, it retrieves detailed stock information, including items currently reserved for orders, items currently in transit, and the total financial value of the stock held at each location.

1.2 Step-by-Step Flow

1. Identify the Product: You provide the unique ID of the product you want to check.
2. Verify Existence: The system confirms that the product exists in the database. If it cannot be found, the system returns an error.
3. Apply Filters: You can narrow down your search by providing specific warehouse details, such as a warehouse ID, name, or location code. You can also choose how many results to see at once using pagination.
4. Retrieve and Calculate: The system gathers the stock data for that product across all relevant warehouses. It then performs real-time calculations to determine the reserved stock, in-transit stock, and the total cost of the inventory on hand.
5. Return Results: The system sends back a summary of the total stock count and a detailed list of the records found, formatted for easy use.

1.3 Key Concepts

- Reserved Quantity: Stock that is currently held for existing customer orders and is no longer available for new sales.
- In-Transit Quantity: Stock that is currently being moved between locations or is on its way from a supplier.
- Total Cost: The calculated financial value of the stock currently sitting in a specific warehouse.
- Pagination: A method to break large lists of data into smaller, manageable pages (using "page" and "limit" settings) to improve performance and readability.
- Filtering: The ability to search for specific warehouse data by using criteria like the warehouse name or location code.

1.4 Business Value

This feature gives inventory managers and sales teams real-time visibility into stock availability. By distinguishing between "on-hand," "reserved," and "in-transit" quantities, the business can make more accurate promises to customers regarding delivery dates and avoid overselling products. Additionally, having the total cost per warehouse readily available helps with financial reporting and inventory valuation.

2. Data

2.1 Overview

This feature provides a simple way to check the current inventory levels for a specific product across all company warehouses. By requesting information for a particular item, the system will return a clear list showing exactly how many units are available at each warehouse location, along with the last time that stock count was updated.

2.2 Step-by-Step Flow

1. Product Verification: The system first checks to ensure the product you are inquiring about actually exists in the database. If the product cannot be found, the system will notify you that the request is invalid.
2. Data Retrieval: Once the product is confirmed, the system searches the inventory records to find all entries associated with that specific item.
3. Information Consolidation: The system gathers the relevant details, matching the stock numbers with the specific names of the warehouses where they are stored.
4. Final Output: The system presents a list containing the warehouse name, the current quantity on hand, and the timestamp of the most recent inventory update.

2.3 Key Concepts

- Product: The specific item you are tracking within the Lumi ERP system.
- Warehouse Stock: The record of how many units of a product are physically located at a specific warehouse.
- Quantity on Hand: The current count of available items ready for use or sale.
- Last Updated: A timestamp indicating when the stock level for that specific warehouse was most recently recorded or modified.

2.4 Business Value

This feature improves operational transparency by allowing staff to quickly identify where stock is located without needing to manually check individual warehouse logs. By providing real-time visibility into inventory distribution, the business can make faster decisions regarding order fulfillment, stock transfers between locations, and replenishment needs, ultimately reducing the risk of overselling or stockouts.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/:id/stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a detailed view of a specific product's inventory levels across all your store locations. It allows you to see not just how much stock is currently on hand, but also how much is reserved for orders or currently in transit. The system automatically calculates the total value of the stock based on your company's specific cost settings, providing a clear snapshot for inventory management.

1.2 Step-by-Step Flow

1. Verification: The system first confirms that the requested product exists in the database. If it cannot be found, the request is stopped.
2. Configuration Check: The system checks your company's global settings to determine how to calculate the "average cost" of the product (either using a company-wide average or a store-specific cost).
3. Data Retrieval: The system gathers the base stock information for the product across all stores, applying any filters you provided (such as specific store IDs or codes) and organizing the results into pages.
4. Snapshot Integration: The system pulls in real-time data regarding items currently reserved for customers and items currently in transit to those stores.
5. Calculation: For each store, the system calculates the total cost of the inventory on hand and aggregates the reserved and in-transit quantities.
6. Filtering and Finalization: If you requested to hide items with zero stock, the system removes those from the list. Finally, it presents the detailed store-by-store breakdown along with a summary of the total quantity across all locations.

1.3 Key Concepts

- Reserved Stock: Items that are currently held for existing customer orders and are no longer available for general sale.
- In-Transit Stock: Items that have been ordered or transferred but have not yet arrived at the store location.
- Effective Cost: The unit price used to calculate the total value of your stock, which adjusts automatically based on whether your company uses a global average or store-specific pricing.
- Pagination: A method of breaking large lists of data into smaller, manageable pages to ensure the system remains fast and responsive.
- Stock Visibility Filter: An option to toggle whether you want to see every store location or only those that currently have items in stock.

1.4 Business Value

This feature empowers store managers and inventory planners to make informed decisions by providing a "single source of truth" for product availability. By consolidating on-hand, reserved, and in-transit quantities into one view, it reduces the risk of overselling and helps teams identify which locations need stock replenishment. The automated cost calculation ensures that financial reporting remains consistent with your company's accounting policies without requiring manual data entry.

2. Data

2.1 Overview

This feature provides a comprehensive stock report for a specific product across all company stores. It aggregates real-time inventory data, including current quantities, reserved items, and stock currently in transit. The report is designed to be flexible, allowing users to filter by specific stores or store codes, and it automatically calculates the total financial value of the stock based on your company's specific cost-accounting settings.

2.2 Step-by-Step Flow

1. Validation: The system first confirms that the requested product exists in the database. If the product cannot be found, the request is stopped.
2. Cost Configuration Check: The system checks your company settings to determine how to calculate the "average cost" of the product. It will either use a global company-wide average or the specific average cost recorded for each individual store.
3. Data Aggregation: The system gathers data from multiple sources, including current stock levels, pending reservations, and items currently in transit. It joins this information with store details to create a unified view.
4. Filtering: The system applies any requested filters (such as specific store IDs or codes). It also checks if you want to see all stores or only those that currently have stock on hand.
5. Calculation and Formatting: The system calculates the total financial value for each store (quantity multiplied by the effective cost) and generates a summary of the total quantity across all included locations.
6. Delivery: The final report is returned, organized by store, including the calculated totals and summary metrics.

2.3 Key Concepts

- Effective Cost: The unit cost used for financial reporting, which is determined by your company's preference to either use a single global average or store-specific averages.
- Reserved Stock: Items that are currently held for orders but have not yet been shipped or deducted from the physical inventory count.
-

In-Transit Stock: Items that have been ordered or transferred but have not yet arrived at the destination store.

– Stock Aggregation: The process of combining physical inventory, reservations, and in-transit data into a single, easy-to-read report for each store.

2.4 Business Value

This feature provides store managers and inventory planners with a "single source of truth" for product availability. By consolidating physical stock, reservations, and in-transit items, the business can make more accurate replenishment decisions and avoid stockouts. Furthermore, by automating the cost calculation based on company policy, the system ensures that financial reporting remains consistent and accurate across all locations without requiring manual data manipulation.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stores

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get Stores" feature provides a secure way for authorized users to retrieve a comprehensive list of all store locations currently registered in the Lumi ERP system. This tool ensures that your team can easily access store details, such as names and operational status, to support daily business operations and reporting.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and has a valid session before processing the request. If the user is not authorized, the request is denied.
2. Data Retrieval: Once authenticated, the system queries the database to gather all available store records.
3. Data Delivery: The system compiles the store information—including names, location codes, and activity status—and sends it back to the user.
4. Error Handling: If an unexpected issue occurs during the process, the system catches the error and provides a notification that the request could not be completed.

1.3 Key Concepts

- Authentication: A security gate that ensures only verified users can access sensitive business data.
- Store Record: The collection of specific details for a single location, including its unique identifier, name, location code, active status, and the date it was created.
- API: The digital bridge that allows different parts of the Lumi ERP system to communicate and share information.

1.4 Business Value

This feature serves as a foundational building block for the Lumi ERP. By providing a reliable and secure way to pull store data, it enables other parts of the system—and your staff—to maintain an accurate, up-to-date view of the organization's physical footprint. This visibility is essential for effective inventory management, regional reporting, and overall operational oversight.

2. Data

2.1 Overview

The "Get Stores" feature provides a simple way for the Lumi ERP system to retrieve a comprehensive list of all currently active store locations. This functionality allows other parts of the system or authorized users to view store details, such as names and location codes, ensuring that the application always has access to the most up-to-date list of operational business sites.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to retrieve the list of stores.
2. Security Check: The system verifies that the user is authorized to access this information. If the user is not logged in or their session is invalid, the request is denied.
3. Data Retrieval: The system queries the database specifically for stores marked as "active."
4. Data Formatting: The raw database information is organized into a clean, readable format that includes the store's unique ID, name, location code, and status.
5. Response Delivery: The formatted list is sent back to the requester. If a technical error occurs during the database search, the system provides a clear notification that an internal error has occurred.

2.3 Key Concepts

- Active Stores: Only locations currently marked as "active" in the system are returned, ensuring the list remains relevant and excludes closed or archived locations.
- Store Details: The information provided for each location includes its unique identifier, official name, and a specific location code used for internal tracking.
- Error Handling: Built-in safeguards ensure that if the system cannot reach the database, it reports an error rather than providing incomplete or misleading information.

2.4 Business Value

This feature serves as a foundational building block for the Lumi ERP. By providing a reliable and automated way to fetch active store data, it eliminates the need for manual data entry or static lists. This ensures that all departments—from inventory management to financial reporting—are working with a single, accurate source of truth regarding where the business is currently operating.

PATCH /api/products/:id/stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to update the "minimum" and "maximum" stock thresholds for a specific product across multiple store locations simultaneously. By using a bulk update process, the system ensures that inventory settings are adjusted efficiently and consistently across your retail network.

1.2 Step-by-Step Flow

1. Product Verification: The system first confirms that the product you are trying to update actually exists in the database.
2. Data Validation: The system reviews each store update provided in your request to ensure:

* The quantities are positive numbers.

* The minimum threshold is not set higher than the maximum threshold.

* The specific store exists for that product.

* You have the necessary permissions to modify stock settings for those specific stores.

3. Transactional Update: Once all data is validated, the system applies all changes at once. If any part of the update fails, the entire batch is rejected to prevent data inconsistencies.
4. Confirmation: After the update is successfully saved, the system returns the updated stock information for the product across all relevant stores so you can verify the changes.

1.3 Key Concepts

- Bulk Update: The ability to send multiple store-level changes in a single request, reducing the number of interactions needed with the system.
- Transactional Integrity: A "safety-first" approach where the system ensures that either all requested changes are saved successfully, or none of them are, preventing partial or corrupted data.
- Stock Thresholds: The minimum and maximum quantity levels defined for a product at a specific store, used to help manage inventory replenishment and avoid stockouts or overstocking.
- Validation: Automated checks performed by the system to ensure that the data entered is logical (e.g., you cannot have a minimum stock level that is higher than your maximum).

1.4 Business Value

This feature streamlines inventory management by allowing managers to update stock policies for an entire product line across multiple locations in one go. It reduces manual data entry errors through automated validation and

ensures that inventory thresholds remain accurate and reliable, which is critical for maintaining optimal stock levels and supporting effective replenishment planning.

2. Data

2.1 Overview

This feature allows users to update the minimum and maximum stock thresholds for a product across multiple store locations in a single action. By using a "bulk update" approach, the system ensures that all changes are processed together, maintaining data consistency across your inventory records.

2.2 Step-by-Step Flow

1. Request Submission: The system receives a request containing a list of stores and the new minimum and maximum stock levels for each.
2. Validation: The system checks the data to ensure:

* All stock levels are positive numbers.

* The minimum stock level is not set higher than the maximum stock level.

3. Verification: The system confirms that the product exists and that the user has the necessary permissions to modify stock records for the specified stores.
4. Atomic Update: The system applies the changes to the database. Because this happens in a single transaction, either every update is saved successfully, or none of them are—preventing partial or inconsistent data.
5. Confirmation: Once the updates are saved, the system returns the updated stock information for the entire product.

2.3 Key Concepts

- Bulk Update: The ability to send multiple changes in one request, which improves efficiency and ensures all related updates are handled as a single unit of work.
- Atomic Transaction: A safety mechanism that ensures that if any part of the update fails, the entire operation is rolled back, keeping the database in a reliable state.
- Stock Thresholds: The "min" and "max" quantities defined for a product at a specific store, used to trigger reordering or inventory management alerts.
- Validation Rules: Built-in safeguards that prevent invalid data (such as negative numbers or illogical ranges) from being saved to the system.

2.4 Business Value

This feature streamlines inventory management by allowing managers to adjust stock thresholds for multiple locations simultaneously. It reduces the time spent on manual data entry and minimizes the risk of human error through automated validation. Most importantly, the "all-or-nothing" update process ensures that inventory data remains accurate and reliable across the entire organization, preventing discrepancies that could lead to stockouts or overstocking.

GET /api/products/:id/history

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. LOgic

1.1 Overview

This feature provides a way to view the historical purchase prices for a specific product. By retrieving this data, you can see how much you have paid for an item over time, broken down by the different vendors you have worked with. This helps you monitor price fluctuations and evaluate vendor performance.

1.2 Step-by-Step Flow

1. Request Initiation: You provide the unique ID of the product you wish to investigate. You can also specify how many records to see at once (limit) and which page of results to view.
2. Validation: The system checks that the product ID is formatted correctly. If the ID is invalid, the system will notify you of the error.
3. Verification: The system confirms that the product actually exists in your database. If the product cannot be found, the system will return a "Not Found" message.
4. Data Retrieval: The system gathers the purchase history records for that specific product, organizing them from the most recent date to the oldest.
5. Display: The system presents the list of historical prices, including the vendor involved and the date each price was effective.

1.3 Key Concepts

- Purchase Price History: A chronological record of what was paid for a specific item, allowing for trend analysis.
- Pagination: A method of breaking large lists of data into smaller, manageable chunks (pages) to ensure the system remains fast and easy to read.
- Vendor Association: Each price record is linked to a specific vendor, allowing you to compare costs across different suppliers.
- Effective Date: The specific date on which a particular purchase price became active.

1.4 Business Value

- Cost Transparency: Easily track price trends over time to identify when costs are rising or falling.
- Vendor Accountability: Compare historical pricing across different suppliers to ensure you are getting the best value for your purchases.
- Informed Decision Making: Use historical data to negotiate better contracts or plan future procurement budgets with greater accuracy.

2. DATA

2.1 Overview

The Product Price History feature allows users to view a chronological record of purchase prices for a specific product. By retrieving this data, you can see how much you have paid for an item over time and compare pricing across different vendors. The system provides this information in a paginated list, ensuring that even products with long histories are easy to navigate and review.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for the price history of a specific product, including optional settings for how many records to show per page.
2. Validation: The system checks if the requested product exists in the database. If the product ID is invalid, the request is rejected with a "Not Found" error.
3. Parameter Check: The system verifies that the pagination settings (page number and limit) are valid numbers. If they are incorrect, the request is rejected.
4. Data Retrieval: The system fetches the price history records for that product, linking each price to the specific vendor who provided it.
5. Sorting: The records are organized so that the most recent price changes appear at the top of the list.
6. Response: The system returns the requested list of prices along with metadata (such as the total number of records) to help manage the display of the information.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Vendor Association: Linking each price entry to a specific supplier, allowing you to track which vendor offered a particular price at a specific time.
- Effective Date: The specific date and time when a price change was recorded, which serves as the basis for the chronological history.
- Metadata: Supporting information returned with the data, such as the total count of records, which helps the user interface know how many pages of history are available.

2.4 Business Value

This feature provides transparency into procurement costs, enabling better decision-making. By analyzing price trends over time, your team can identify cost fluctuations, evaluate vendor performance, and negotiate better

contracts based on historical data. It transforms raw purchase records into actionable insights, helping you maintain tighter control over your supply chain expenses.

GET /api/store-stock-histories

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Store Stock History API allows authorized users to retrieve a detailed log of stock changes within the Lumi ERP system. This feature provides transparency into inventory movements by allowing users to search, filter, and view a paginated list of historical stock transactions.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the user is logged in and authorized to access the data. If the user is not authenticated, the request is rejected.
2. Parameter Processing: The system collects any filters provided by the user (such as specific stores, products, transaction types, date ranges, or the user who performed the action) and sets up pagination preferences.
3. Data Retrieval: The system searches the stock history database using the provided filters. It organizes the results in reverse chronological order (newest first).
4. Response Delivery: The system returns the requested list of stock history records along with metadata, including the current page number, the number of items per page, and the total count of records found.
5. Error Handling: If an unexpected issue occurs during the search, the system logs the error and provides a notification that the data could not be retrieved.

1.3 Key Concepts

- Stock History: A chronological record of all inventory adjustments, such as additions, removals, or transfers of products.
- Filtering: The ability to narrow down search results by specific criteria, such as a particular store, a specific product, or a timeframe.
- Pagination: A method of breaking large amounts of data into smaller, manageable chunks (pages) to ensure the system remains fast and easy to navigate.
- Authentication: A security check that ensures only verified users can access sensitive inventory data.

1.4 Business Value

This feature provides essential auditability and operational oversight for inventory management. By enabling users to track exactly when, why, and by whom stock levels were changed, businesses can:

- Improve Accountability: Easily identify who performed specific stock adjustments.
- Enhance Accuracy: Quickly investigate inventory discrepancies by reviewing the transaction history.
-

Support Decision Making: Use historical data to identify trends in stock movement, helping to optimize replenishment and reduce waste.

2. Data

2.1 Overview

The "Store Stock History" feature provides a way to retrieve a detailed log of all inventory changes within the system. This tool allows users to audit stock movements by searching through historical records, such as identifying when a specific product was added or removed from a store's inventory, who performed the action, and when it occurred.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view stock history, which may include optional search filters (such as a specific store, product, transaction type, date range, or the user who made the change).
2. Filtering: The system applies the provided search criteria to narrow down the database records. It looks for partial matches on IDs and names, and specific date ranges for when the transactions occurred.
3. Pagination: To ensure the system remains fast and easy to navigate, the results are broken into smaller, manageable pages. The system calculates which specific "slice" of data to show based on the requested page number.
4. Data Retrieval: The system counts the total number of matching records and fetches the specific list of entries for the requested page, sorted from the most recent to the oldest.
5. Response: The system returns the requested list of stock history records along with metadata, which includes the current page number, the number of items per page, and the total count of records found.

2.3 Key Concepts

- Pagination: A method of splitting a large list of data into smaller pages to improve performance and readability.
- Filtering: The ability to narrow down search results based on specific criteria, such as a date range or a specific product ID.
- Transaction Type: A label describing the nature of the stock change (e.g., restock, sale, or adjustment).
- Metadata: Supporting information returned with the data, such as the total number of records, which helps the user interface display the correct page numbers.

2.4 Business Value

This feature is essential for inventory accountability and operational transparency. By providing a searchable, paginated history of stock movements, store managers and auditors can:

- Improve Accuracy: Quickly investigate discrepancies in inventory levels.
- Enhance Accountability: Track exactly who authorized or performed specific stock adjustments.
- Support Reporting: Easily extract data for sales analysis or restocking performance reviews over specific time periods.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/products/brand

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to add a new product brand to the Lumi ERP system. By submitting a brand name and an optional description, the system creates a new entry associated with the user's company. The process includes built-in safeguards to ensure that only authorized users can create brands and that brand names remain unique within the system.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the person making the request is logged in. If the user is not recognized, the request is rejected.
2. Input Validation: The system checks that a brand name has been provided. If the name is missing, the request is rejected.
3. Duplicate Check: The system searches the database to ensure no other brand already exists with the same name. If a match is found, the request is rejected to prevent duplicates.
4. Data Preparation: If all checks pass, the system assigns a unique identifier to the brand, links it to the user's company, and records the current date and time.
5. Saving: The new brand information is saved to the database. Upon success, the system confirms the creation by returning the full details of the new brand.

1.3 Key Concepts

- Authentication: A security check that confirms the identity of the user before allowing them to perform actions.
- Validation: A quality control step that ensures required information is present and follows the correct format before processing.
- Uniqueness Constraint: A rule that prevents the system from creating two brands with the exact same name, ensuring data integrity.
- Persistence: The process of permanently saving the new brand information into the company's database.

1.4 Business Value

This feature streamlines product catalog management by providing a reliable, automated way to register new brands. By enforcing unique naming and linking brands directly to the correct company, the system reduces manual data entry errors and ensures that product information remains organized and consistent across the ERP platform.

2. Data

2.1 Overview

This feature allows users to add a new product brand to the Lumi ERP system. When a user submits a brand name and an optional description, the system ensures the information is valid and unique to their specific company before saving it to the database. This helps maintain organized product catalogs and prevents duplicate entries within a company's brand list.

2.2 Step-by-Step Flow

1. Validation: The system checks that a brand name has been provided. If the name is missing, the request is rejected.
2. Uniqueness Check: The system searches the existing records for the user's company to ensure no other brand already uses that same name. If a match is found, the request is rejected to prevent duplicates.
3. Data Preparation: If the checks pass, the system gathers the brand name, the optional description, and the user's company information.
4. Persistence: The system assigns a unique identifier and a timestamp to the new brand and saves it permanently to the database.
5. Confirmation: Upon successful saving, the system confirms the creation of the new brand.

2.3 Key Concepts

- Brand: A specific product label or category managed by a company within the ERP system.
- Company Scope: The system ensures that brands are unique only within the context of the specific company that owns them, allowing different companies to potentially use the same brand names.
- Validation: The process of ensuring that required information (like the brand name) is present before processing the request.
- Conflict Prevention: A safeguard that stops the system from creating two brands with the exact same name for the same company.

2.4 Business Value

This feature provides a structured way for businesses to manage their product portfolio. By enforcing naming consistency and preventing duplicate entries, it ensures that inventory and product reporting remain accurate and reliable. It also provides a secure, authenticated way for users to manage their own company's data without interfering with other organizations using the platform.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/products/tags

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to create new product tags within the Lumi ERP system. By assigning tags to products, your team can better categorize, organize, and filter inventory items. The system ensures that each tag is unique to your company and provides clear feedback if a request is incomplete or unauthorized.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the person making the request is logged in. If they are not, the request is rejected.
2. Validation: The system checks that a name has been provided for the tag. If the name is missing, the request is rejected.
3. Duplicate Check: The system searches your company's existing tags to ensure a tag with that specific name does not already exist. If a duplicate is found, the request is rejected to prevent clutter.
4. Creation: If all checks pass, the system saves the new tag (including its name and optional description) to the database and assigns it a unique identifier and timestamp.
5. Confirmation: The system returns the details of the newly created tag to confirm the process was successful.

1.3 Key Concepts

- Product Tag: A label used to categorize products, making them easier to find and manage within the ERP.
- Authentication: A security step that confirms the identity of the user before allowing them to modify company data.
- Validation: A quality-control step that ensures the information provided is complete and follows the required format.
- Duplicate Prevention: A safeguard that prevents the creation of multiple tags with the same name, keeping your data organized and consistent.

1.4 Business Value

- Improved Organization: Standardizes how products are categorized across the organization, leading to better inventory management.
- Data Integrity: Prevents the creation of duplicate or incomplete records, ensuring your product database remains clean and reliable.
- Security: Ensures that only authorized users can modify product classification settings, protecting your business data from unauthorized changes.

2. Data

2.1 Overview

This feature allows users to create custom tags for their products within the Lumi ERP system. By assigning tags, businesses can better organize, categorize, and filter their product inventory. The system ensures that each tag is unique to the user's company, preventing duplicate labels and maintaining data integrity.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to perform the action.
2. Duplicate Validation: The system checks if a tag with the requested name already exists for the user's company.
3. Error Handling: If a tag with that name already exists, the system rejects the request to prevent duplicates.
4. Data Creation: If the name is unique, the system creates the new tag, associating it with the user's company and recording the creation time.
5. Confirmation: The system confirms the successful creation of the tag and provides the details of the newly created item.

2.3 Key Concepts

- Product Tag: A label used to categorize or group products, making them easier to manage and search within the ERP.
- Company Scope: A security measure that ensures tags created by one company are kept separate from those of another, ensuring data privacy and relevance.
- Validation: A safeguard that checks for missing information or duplicate entries before saving data to the system.

2.4 Business Value

- Improved Organization: Enables teams to classify products in a way that aligns with their specific business processes (e.g., by season, department, or status).
- Data Integrity: Prevents clutter and confusion by ensuring that companies do not accidentally create duplicate tags.
- Operational Efficiency: Streamlines product management by allowing users to quickly define and apply custom labels, which improves searchability and reporting across the inventory.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/type

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of product types. It is designed to support user interface elements like dropdown menus, search filters, and lookup fields. The tool allows users to browse through product types efficiently by supporting pagination (viewing results in smaller chunks) and a search function to quickly find specific types by name.

1.2 Step-by-Step Flow

1. Request Processing: The system receives a request to list product types. It checks for pagination settings (how many items to show per page and which page to display) and any search text provided.
2. Parameter Normalization: The system standardizes the pagination settings. If multiple settings for "number of rows" are provided, it follows a specific priority order to ensure consistency, defaulting to 20 items per page if no preference is set.
3. Validation: The system verifies that the requested page number and row count are valid (must be at least 1). If these numbers are invalid, the request is rejected.
4. Data Retrieval: The system searches the database for product types. If a search term was provided, it filters the list to show only matching names (ignoring capitalization). The results are automatically sorted alphabetically.
5. Response:

* If matches are found, the system returns the list of product types.

* If a specific search was performed but no matches were found, the system informs the user that no results were found.

* If an error occurs, the system provides an appropriate error message.

1.3 Key Concepts

– Pagination: A method of breaking a large list of data into smaller, manageable pages to improve performance and readability.
– Case-Insensitive Search: A search feature that finds matches regardless of whether the user types in uppercase or lowercase letters.
– Normalization: The process of prioritizing different input settings to ensure the system always uses a single, consistent rule for displaying data.
– Alphabetical Sorting: The system automatically organizes the product types from A to Z to make them easier to navigate.

1.4 Business Value

This feature improves the user experience by making it faster and easier to find and select product types within the Lumi ERP system. By providing a searchable and paginated list, the system remains responsive even as the number of product types grows, ensuring that users can quickly locate the information they need without scrolling through long, unorganized lists.

2. Data

2.1 Overview

The "Get Product Types" feature provides a way for the system to retrieve a list of available product categories. This is primarily used to populate dropdown menus, search filters, or lookup fields within the Lumi ERP interface. The feature is designed to be flexible, allowing users to search for specific types by name and navigate through large lists using pagination.

2.2 Step-by-Step Flow

1. Request Receipt: The system receives a request for product types. It checks for optional search terms and pagination settings (which page to show and how many items per page).
2. Parameter Normalization: The system standardizes the pagination settings. If multiple conflicting settings are provided, it prioritizes the "rows" setting to determine the page size.
3. Validation: The system ensures that the requested page number and the number of rows are valid (must be 1 or greater). If these are invalid, the request is rejected.
4. Data Retrieval: The system searches the database for product types that match the search term (if provided). It ignores capitalization during this search.
5. Sorting and Formatting: The retrieved list is sorted alphabetically by name.
6. Response:

* If matches are found, the system returns the list along with metadata (such as the total count of items).

* If a search term was used but no matches were found, the system returns a "Not Found" status.

2.3 Key Concepts

– Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and usability.

– Case-Insensitive Search: A search feature that finds matches regardless of whether the user types in uppercase or lowercase letters.

–

Normalization: The process of standardizing input parameters so the system consistently interprets user requests, even if different labels (like "rows" vs "pagesize") are used.

– Metadata: Additional information returned with the data, such as the total number of records available, which helps the user interface display accurate page numbers.

2.4 Business Value

This feature improves the user experience by making it easy to find and select product types within the ERP. By supporting search and pagination, the system remains fast and responsive even as the number of product types grows over time. It ensures that data is presented in a clean, organized, and predictable manner, reducing the time users spend searching for information.

BUSINESS REQUIREMENTS DOCUMENT

PUT /api/voucher_flexibles/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to update the details of an existing "flexible voucher" within the Lumi ERP system. By providing a specific voucher ID and the updated information (such as the name, description, value, or SKU), users can keep their voucher records accurate and up-to-date.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and possesses the necessary "write" permissions to modify voucher data.
2. Request Processing: The system identifies the specific voucher to be updated using the ID provided in the web address.
3. Validation: The system checks that the information provided in the request is properly formatted and complete.
4. Uniqueness Check: If the user is changing the voucher's SKU, the system ensures that the new SKU is not already being used by another voucher to prevent duplicates.
5. Update: If all checks pass, the system updates the voucher record with the new details and records the time of the update.
6. Confirmation: The system returns the updated voucher information to the user to confirm the changes were successful.

1.3 Key Concepts

- Flexible Voucher: A customizable voucher type within the ERP that can be modified to suit changing business needs.
- SKU (Stock Keeping Unit): A unique identifier for the voucher; the system enforces that no two vouchers share the same SKU.
- Authentication: The process of verifying that the person making the request is a recognized user of the system.
- Authorization: The process of ensuring the verified user has the specific "write" permission required to perform updates.
- Validation: A safety check to ensure that the data provided (like names or values) meets the system's required format and rules.

1.4 Business Value

This feature provides operational flexibility by allowing administrators to correct or adjust voucher details as business requirements evolve. By enforcing strict validation and uniqueness checks, the system maintains data integrity, ensuring that voucher records remain reliable, organized, and free of conflicting information.

2. Data

2.1 Overview

This feature allows authorized users to update the details of an existing "flexible voucher" within the Lumi ERP system. By providing a unique identifier for the voucher and the updated information, users can modify attributes such as the voucher's name, description, value, and SKU (Stock Keeping Unit). The system includes built-in safeguards to ensure data integrity, such as verifying that the voucher exists before attempting an update and preventing duplicate SKU assignments.

2.2 Step-by-Step Flow

1. Authentication and Authorization Check: The system verifies that the user is logged in and possesses the necessary permissions to modify voucher records.
2. Voucher Verification: The system checks if a voucher matching the provided unique identifier exists in the database. If it cannot be found, the request is rejected.
3. Conflict Detection: The system checks the provided SKU against all other existing vouchers. If another voucher is already using that SKU, the update is blocked to prevent data conflicts.
4. Data Validation: The system ensures the provided information meets all required formatting and field rules.
5. Record Update: Once all checks pass, the system updates the voucher record with the new information and records the current date and time as the last modification timestamp.
6. Confirmation: The system returns the updated voucher details to the user to confirm the changes were successful.

2.3 Key Concepts

- Flexible Voucher: A specific type of voucher entity within the ERP that contains details like a name, description, monetary value, and a unique SKU.
- SKU (Stock Keeping Unit): A unique identifier used to track specific items; the system enforces that no two vouchers can share the same SKU.
- Unique Identifier (ID): A permanent, system-generated reference used to pinpoint the exact voucher record that needs to be updated.
-

Data Integrity: The process of ensuring that updates do not create errors, such as duplicate identifiers or invalid data entries.

2.4 Business Value

This feature provides administrative flexibility, allowing the business to adjust voucher details (such as value or descriptions) as marketing strategies or financial requirements evolve. By enforcing strict validation and conflict checks, the system prevents human error and ensures that voucher data remains accurate and reliable for reporting and financial tracking purposes.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/voucher_flexibles/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to retrieve the specific details of a "flexible voucher" by using its unique identifier. It ensures that sensitive voucher information is only accessible to the correct owner and provides clear feedback if a request cannot be completed due to security, permission, or availability issues.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the person making the request is logged in and authorized to use the system.
2. Identification: The system identifies which specific voucher is being requested based on the unique ID provided.
3. Data Retrieval: The system searches the database to locate the voucher record associated with that ID.
4. Verification: If the voucher is found, the system confirms that the person requesting the information has the necessary permissions to view that specific voucher.
5. Data Delivery: If all checks pass, the system returns the voucher's details, including its code, monetary value, currency, status, expiration date, and creation date.
6. Error Handling: If the voucher does not exist, the user lacks permission, or the system encounters an issue, an appropriate error message is returned to explain why the request could not be fulfilled.

1.3 Key Concepts

- Voucher Flexible: A specific type of digital voucher within the Lumi ERP system that holds a monetary value and has an expiration date.
- Authentication: The process of verifying the identity of the user to ensure they are allowed to interact with the system.
- Authorization: The process of checking if an authenticated user has the specific rights to view a particular piece of data (in this case, a specific voucher).
- Unique Identifier (ID): A digital "fingerprint" used to ensure the system retrieves the exact voucher requested without confusion.

1.4 Business Value

This feature provides a secure and reliable way for users to manage their flexible vouchers. By enforcing strict authentication and permission checks, it protects sensitive financial data from unauthorized access. Additionally, by providing clear status responses (such as "Not Found" or "Forbidden"), it helps users and integrated systems troubleshoot issues quickly, ensuring a smooth and transparent experience when managing voucher assets.

2. Data

2.1 Overview

This feature allows authorized users to retrieve the specific details of a "flexible voucher" by using its unique identifier. It ensures that sensitive voucher information is protected by verifying both the user's identity and their specific ownership rights before displaying any data.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view a specific voucher using its unique ID.
2. Authentication Check: The system verifies that the user is logged in. If the user is not authenticated, the request is rejected.
3. Data Retrieval: The system searches the database for a voucher record that matches the provided ID. If no record is found, the system reports that the voucher does not exist.
4. Permission Verification: Once the voucher is located, the system checks if the current user is the rightful owner of that voucher.
5. Access Decision:

* If the user is the owner, the system displays the voucher details (such as the code, amount, currency, status, and expiry date).

* If the user is not the owner, the system denies access to protect the data.

6. System Safeguards: Throughout the process, the system monitors for errors (such as server issues) or excessive request rates, providing appropriate feedback if these limits are reached.

2.3 Key Concepts

- Voucher Flexible: A digital asset or credit record within the Lumi ERP system that contains specific financial details like balance, currency, and expiration date.
- Authentication: The process of confirming the user's identity to ensure they are a valid system user.
- Authorization: The security check that ensures a user has the specific permission to view a particular piece of data (in this case, verifying ownership).
- Unique Identifier: A specific code or ID assigned to each voucher to ensure the system retrieves the exact record requested.

2.4 Business Value

This feature provides a secure and efficient way for customers to manage their flexible vouchers. By enforcing strict ownership checks, the system prevents unauthorized access to financial data, ensuring privacy and security. Additionally, by providing clear responses for missing records or permission issues, it creates a reliable and predictable experience for users interacting with the Lumi ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/warehouses

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get Warehouses" feature provides a way for external systems to retrieve a list of warehouse records from the Lumi ERP. It is designed to be flexible, allowing users to filter, sort, and paginate through large amounts of data efficiently. By default, the system returns active warehouses, but users can customize their requests to find specific information based on update dates or status.

1.2 Step-by-Step Flow

1. Request Validation: The system receives the request and checks that all provided parameters (like page numbers or limits) are valid. If the inputs are incorrect, it returns an error.
2. Applying Filters: The system applies any requested filters, such as showing only active or inactive warehouses, or narrowing the list to records updated after a specific date.
3. Sorting: The system organizes the results based on the user's preference (e.g., by name or date) and direction (ascending or descending).
4. Pagination: The system limits the number of results returned at once to ensure performance. It supports both standard page-based navigation and a "cursor" method for smoother data retrieval.
5. Data Delivery: The system compiles the final list of warehouses and sends it back to the user.

1.3 Key Concepts

- Pagination: A method to break a large list of data into smaller, manageable chunks (pages) to improve system performance.
- Cursor (after_id): A specific identifier used to fetch the "next" set of data. This is more reliable than page numbers when dealing with very large or frequently changing datasets.
- Filtering: The ability to narrow down the list of warehouses based on specific criteria, such as whether they are currently active or when they were last modified.
- Sorting: The ability to arrange the list in a specific order, such as alphabetically by name or chronologically by the last update time.

1.4 Business Value

This feature enables seamless integration between the Lumi ERP and other business tools. By providing robust filtering and pagination, it ensures that external systems can quickly and reliably sync warehouse data without overwhelming the server. This allows for accurate inventory management and real-time visibility into warehouse operations across the entire business ecosystem.

2. Data

2.1 Overview

The `GET /api/warehouses` feature provides a flexible way for external systems to retrieve a list of warehouses from the Lumi ERP. It is designed to handle large amounts of data efficiently by allowing users to filter, sort, and paginate the results. The system includes built-in safeguards to ensure requests are valid and to prevent performance issues.

2.2 Step-by-Step Flow

1. Request Validation: When a request is received, the system first checks that all provided parameters (such as page limits) are within acceptable ranges. If the request is invalid, it returns an error.
2. Filtering: The system applies any requested filters, such as showing only active warehouses or only those updated after a specific date.
3. Pagination: The system determines how to return the data:

* Standard Pagination: Uses page numbers and a set limit per page.

* Cursor-based Pagination: Uses a specific ID (cursor) to fetch the next set of records, which is more reliable for very large datasets.

4. Sorting: The system organizes the results based on the user's preference (e.g., by name or last update date) and direction (ascending or descending).
5. Data Retrieval: The system fetches the final list from the database and returns it to the user. If an unexpected error occurs during this process, the system logs the issue and returns a server error message.

2.3 Key Concepts

- Pagination: A method to break a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Cursor-based Pagination (Keyset): A high-performance way to navigate large lists by using a specific record ID as a "bookmark" to fetch the next set of items, rather than relying on page numbers.
- Filtering: The ability to narrow down the list of warehouses based on specific criteria, such as their status (active/inactive) or when they were last modified.
- Sorting: The ability to arrange the list in a specific order, such as alphabetically by name or chronologically by the last update time.
- Validation: A security and quality check that ensures incoming requests do not exceed system limits (e.g., capping the number of results per request to 300) to maintain system stability.

2.4 Business Value

This feature enables seamless integration between the Lumi ERP and other business tools. By providing robust filtering and pagination, it ensures that users can quickly and reliably access the specific warehouse information they need without overwhelming the system, even as the number of warehouses grows over time.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/products/brand

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of product brands. It is designed to support user interface elements like dropdown menus, search filters, and lookup fields. The tool allows users to view all available brands or search for specific ones by name, with built-in pagination to ensure the system remains fast and responsive even as the list of brands grows.

1.2 Step-by-Step Flow

1. Parameter Setup: The system checks for pagination settings (how many items to show per page and which page to display). If no specific settings are provided, it defaults to showing 20 items per page.
2. Validation: The system ensures that the requested page number and the number of items per page are valid positive numbers. If they are not, it returns an error.
3. Filtering: If a search term is provided, the system prepares to filter the brand list to include only those that match the search text (ignoring capitalization).
4. Data Retrieval: The system fetches the requested brands from the database, sorts them alphabetically by name, and applies the pagination limits.
5. Response:

* If brands are found, the system returns the list.

* If a specific search was performed but no matches were found, the system notifies the user that no results were found.

* If any errors occur during the process, the system returns an appropriate error message.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Case-Insensitive Search: A search feature that finds matches regardless of whether the user types in uppercase or lowercase letters (e.g., searching for "nike" will also find "Nike").
- Normalization: The process of standardizing different input names (like "rows," "pagesize," and "pageLimit") so the system treats them all as the same instruction for how many items to display.
- Sorting: The automatic organization of the brand list in alphabetical order (A-Z) to make it easier for users to find what they need.

1.4 Business Value

This feature improves the user experience by providing a reliable and efficient way to browse and select product brands. By including search and pagination capabilities, it ensures that staff can quickly locate specific brands within large catalogs without system slowdowns. This standardization helps maintain data consistency across different parts of the Lumi ERP platform where brand selection is required.

2. Data

2.1 Overview

This feature provides a way for the system to retrieve a list of product brands. It is designed to support user interface elements like dropdown menus or search filters, allowing users to quickly find and select specific brands. The feature includes built-in search capabilities and pagination to ensure the system remains fast and responsive even as the number of brands grows.

2.2 Step-by-Step Flow

1. Request Processing: The system receives a request for the brand list. It checks the provided settings for page number and the number of items to display.
2. Validation: The system ensures that the requested page number and row count are valid (must be at least 1). If the inputs are invalid, the request is rejected.
3. Filtering: If a search term is provided, the system filters the brand list to include only those that match the search text (ignoring capitalization).
4. Sorting: The system organizes the resulting list of brands in alphabetical order.
5. Pagination: The system calculates which specific slice of the list to show based on the requested page and row count.
6. Data Retrieval: The system gathers the requested brands and calculates the total count of available brands to help the user interface manage navigation.
7. Response: The system returns the list of brands along with the pagination details. If a search was performed but no matches were found, the system indicates that no results are available.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Case-Insensitive Search: A search feature that finds matches regardless of whether the user types in uppercase or lowercase letters.
-

Normalization: The process of standardizing input settings (such as choosing between different names for "row count") so the system can process them consistently.

- Metadata: Additional information returned with the data, such as the total number of records, which helps the front-end application display page numbers correctly.

2.4 Business Value

This feature improves the user experience by providing a reliable and efficient way to browse or search for product brands. By implementing pagination and sorting, we ensure that the application remains performant and easy to navigate, reducing the time users spend searching for information. This standardized approach also makes it easier for developers to integrate brand selection into various parts of the ERP system.

BUSINESS REQUIREMENTS DOCUMENT

Product Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Product Schema feature provides a unified way to retrieve a complete "360-degree" view of a product within the Lumi ERP system. Instead of looking up information in several different places, this feature consolidates data from various parts of the system—such as store inventory, warehouse stock, branding, product types, and descriptive tags—into a single, comprehensive record. This ensures that whenever you need to view, create, or update a product, you are working with a consistent and complete set of information.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a specific product, identifying the store and the product ID.
2. Data Consolidation: The system performs a single, unified search across multiple data sources, including:

* Core Product Details: Name, SKU, category, and pricing.
* Store & Warehouse Stock: Current quantities, reserved items, and available stock levels.
* Categorization: Associated brand, product type, and descriptive tags.

3. Calculation: The system automatically calculates the "available quantity" by subtracting reserved and consignment items from the total warehouse inventory.
4. Formatting: The gathered data is organized into a structured format (JSON) that includes all these details in one response.
5. Pagination: If the request involves a list of products, the system applies limits and offsets to ensure the data is returned in manageable chunks, improving performance.

1.3 Key Concepts

– Consolidated Query: A method of gathering data from multiple related tables (like inventory, brands, and tags) in one go, rather than making several separate requests.
– Available Quantity: A calculated value representing the stock actually ready for sale, derived by taking the total inventory and subtracting items that are reserved or held on consignment.
– Pagination: A technique used to break large lists of data into smaller, numbered pages, which helps the software run faster and makes the information easier to navigate.
– JSON Schema: The standardized "blueprint" or structure that defines exactly what information is included in a product record, ensuring consistency across the entire ERP.

1.4 Business Value

* Single Source of Truth: By consolidating data, you avoid discrepancies between different reports or screens, ensuring that the product information you see is always accurate and up-to-date.
* Improved Efficiency: Staff can access all necessary product details—from pricing to warehouse availability—in one view, reducing the time spent switching between different modules or screens.
* Better Inventory Management: With real-time visibility into "available" versus "reserved" stock, the business can make more informed decisions about purchasing, transfers, and sales, preventing stockouts or overstocking.
* Scalability: The use of pagination ensures that as your product catalog grows, the system remains fast and responsive, regardless of how many thousands of items you manage.

BUSINESS REQUIREMENTS DOCUMENT

Common Standard Response JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Common Standard Response" feature establishes a universal language for how the Lumi ERP system communicates with its users and other software. By standardizing the format of every response—whether it is a successful data retrieval or an error message—we ensure that the system behaves predictably. This consistency makes it easier for our development teams to build reliable features and ensures that the user experience remains stable across the entire platform.

1.2 Step-by-Step Flow

1. Request Processing: When a user or system interacts with the Lumi ERP, the system processes the request.
2. Outcome Determination: Based on the result of that request, the system identifies the appropriate status (e.g., success, validation error, or system conflict).
3. Standardized Formatting: The system wraps the result into a pre-defined, consistent structure. This ensures that regardless of the outcome, the information provided (such as status codes, error messages, or data) is always located in the same place.
4. Response Delivery: The system sends this structured response back to the user or requesting application, allowing the receiving end to interpret the result immediately without needing custom logic for every different scenario.

1.3 Key Concepts

- Standardized Response: A consistent "envelope" for all information sent back by the system, ensuring that developers and systems always know where to find specific details.
- Status Codes: Numerical indicators that tell the system exactly what happened (e.g., "201" for a successful creation, "404" if something is missing, or "429" if the system is being overwhelmed by too many requests).
- Semantic Validation: A check performed by the system to ensure that even if a request is formatted correctly, the information inside makes logical sense (e.g., ensuring a date is in the future when required).
- Conflict Handling: A specific response used when a user tries to perform an action that clashes with the current state of the system, such as trying to update a record that has already been changed by someone else.

1.4 Business Value

- Reduced Development Time: Because every response follows the same pattern, developers spend less time writing custom code to handle different types of system messages.
- Improved System Reliability: Standardized error handling makes it easier to identify and fix issues, leading to a more stable and robust ERP platform.

- Better User Experience: Consistent responses allow the interface to provide clearer, more helpful feedback to users when something goes wrong, reducing frustration and confusion.
- Easier Integration: Third-party tools and internal modules can connect to the Lumi ERP more easily because they can rely on a predictable, unchanging communication format.

BUSINESS REQUIREMENTS DOCUMENT

Voucher Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Voucher Schema feature provides a structured way to manage vouchers within the Lumi ERP system. It defines how vouchers are created, stored, and retrieved, ensuring that each voucher is correctly linked to a product and configured with specific rules regarding where it can be sold and redeemed. This feature also includes logic to automatically determine the current status of a voucher based on its validity dates.

1.2 Step-by-Step Flow

1. Voucher Definition: A voucher is defined by its core settings, including its type (standard, batch, or flexible), pricing, and whether it is restricted to members.
2. Product Association: Every voucher is linked to a specific product, allowing the system to pull in relevant product details like the SKU and name for reporting and display.
3. Location Configuration: The system determines the "scope" for selling and redeeming the voucher. If the scope is set to "all," the voucher is valid at every store. If set to "specific," the system references a list of authorized stores.
4. Data Retrieval: When a user requests a list of vouchers, the system gathers the voucher details, joins them with the associated product information, and aggregates the list of authorized stores (if applicable).
5. Status Calculation: As the list is generated, the system checks the current date against the voucher's expiration date to automatically flag the status as "active," "inactive," or "expired."

1.3 Key Concepts

- Voucher Scope: A setting that defines whether a voucher is available at all locations or restricted to a specific subset of stores.
- Product Linkage: The connection between a voucher and a product, ensuring that voucher data is always associated with a recognized item in the inventory.
- Dynamic Status: An automated check that updates a voucher's status to "expired" if the current date has passed the defined validity period.
- Aggregated Location Data: A feature that combines multiple store names into a single, readable list for the user, rather than showing individual database records.

1.4 Business Value

- Operational Efficiency: By automating the status calculation and location aggregation, staff no longer need to manually track which vouchers are expired or where they can be used.
- Improved Accuracy: Centralizing the voucher configuration ensures that pricing, member restrictions, and location rules are applied consistently across the entire organization.

- Better Reporting: Linking vouchers to products allows for clearer insights into sales performance and redemption trends, helping the business make data-driven decisions about future promotions.

BUSINESS REQUIREMENTS DOCUMENT

Service Product Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Service Product feature provides a structured way to manage service-based offerings within the Lumi ERP system. It allows users to create, edit, and view service records—such as labor or specialized tasks—while ensuring that financial details like taxes, accounting codes, and pricing are accurately captured and linked to the broader finance module.

1.2 Step-by-Step Flow

1. Accessing the Form: When creating a new service or editing an existing one, the system retrieves a form containing all necessary fields (such as SKU, name, price, and tax settings) along with pre-populated dropdown options for categories, tags, and financial accounts.
2. Data Entry: Users fill in the service details. The system supports flexible pricing (open price) and time estimation (open estimated time) to accommodate services that may vary by transaction.
3. Saving Data: When the user saves, the system performs a secure, "all-or-nothing" update. It saves the core service information and synchronizes any associated tags to ensure the record is always consistent.
4. Viewing Records: Users can view a paginated list of all services, which displays key information like the name, price, and tax status. For a deeper look, the detail view provides the full record, including audit information (who created or updated the service) and calculated fields like the price excluding tax.

1.3 Key Concepts

- Service Product: A record representing a non-physical offering (service) that can be sold, tracked, and taxed within the ERP.
- Financial Integration: The feature pulls data from the Finance module (such as tax rates, accounting codes, and units of measure) to ensure that every service is correctly categorized for accounting purposes.
- Open Price/Time: Settings that allow a service to have a flexible price or duration, which can be defined at the moment a transaction occurs rather than being fixed in the product catalog.
- Atomic Save: A safety mechanism that ensures that if a service is updated, both the service details and its associated tags are saved successfully together, preventing data mismatches.
- Audit Trail: Automatic tracking of who created or last modified a service record and when, providing accountability for all changes.

1.4 Business Value

This feature centralizes service management, reducing manual entry errors by providing standardized dropdowns for financial and categorical data. By integrating directly with the Finance module, it ensures that tax calculations and accounting entries are consistent across the business. Additionally, the flexibility to use "open" pricing and

timing allows the business to handle custom service requests efficiently without needing to create unique product records for every minor variation.

BUSINESS REQUIREMENTS DOCUMENT

Warehouse History JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Warehouse History feature provides a structured way for the Lumi ERP system to track and display the movement of stock for specific products. It allows the system to record every change in quantity—such as deliveries, orders, or balance adjustments—and provides a clear, organized history of these events. Additionally, the feature includes a helper function to retrieve a list of all available warehouses, ensuring users can easily select the correct location when viewing or managing stock data.

1.2 Step-by-Step Flow

1. Warehouse Selection: The system retrieves a complete list of all warehouses, including their unique IDs and names, to populate selection menus in the user interface.
2. Product History Request: When a user selects a specific product, the system requests its stock history.
3. Data Filtering and Sorting: The system searches the database for all records associated with that specific product. It automatically sorts these records by date, showing the most recent changes first.
4. Pagination: To ensure the system remains fast and responsive, the history is delivered in manageable chunks (pages) rather than loading all records at once.
5. Display: The retrieved data is presented in a standardized format, showing details like the type of transaction, the quantity changed, who made the change, and any associated notes.

1.3 Key Concepts

- Stock History: A chronological log of every event that impacts the quantity of a product in a warehouse (e.g., a new delivery or a completed sales order).
- Transaction Type: A category assigned to each stock change, such as "Purchase Delivery" or "Sales Delivery," which helps users quickly identify the nature of the movement.
- Pagination: A method of breaking large amounts of data into smaller, easier-to-read pages to improve system performance.
- Reference Code: An optional identifier (like an invoice or order number) linked to a stock change to help with auditing and cross-referencing.

1.4 Business Value

- Improved Accountability: By tracking who created a record and when, the business gains full visibility into stock adjustments, reducing errors and unauthorized changes.
- Enhanced Auditability: The inclusion of transaction types and reference codes makes it significantly easier for staff to reconcile inventory levels and investigate discrepancies.
-

Better Decision Making: With a clear, sorted history of stock movements, managers can identify trends in product demand and warehouse efficiency.

- User Efficiency: Standardizing how warehouse and stock data is retrieved ensures that the interface remains consistent and fast, allowing staff to find the information they need without unnecessary delays.

BUSINESS REQUIREMENTS DOCUMENT

Store Stock History Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Store Stock History feature provides a comprehensive audit trail of inventory changes across your retail locations. It allows users to track exactly how and when stock levels for specific products have increased or decreased. By connecting individual store data with historical movement records, this feature enables better inventory oversight, reporting, and reconciliation.

1.2 Step-by-Step Flow

1. Filtering: The system accepts search criteria, including the store name, specific product ID, the type of transaction (e.g., sales or transfers), and a specific date range.
2. Data Retrieval: The system gathers data from three interconnected sources: the history of stock changes, the current stock levels, and the store details.
3. Calculation: The system automatically calculates the net change in quantity (total increases minus total decreases) for the filtered results.
4. Organization: The results are sorted based on your preferences (such as by date or store name) and organized into manageable pages to ensure the interface remains fast and easy to navigate.
5. Display: The final output provides a list of individual stock movements, the total number of records found, and the net quantity change for the selected period.

1.3 Key Concepts

- Store Stock History: A chronological log of every inventory adjustment, capturing the "who, what, when, and why" of stock changes.
- Net Quantity Change: A summary calculation that shows the overall impact on inventory (total additions minus total subtractions) for a specific search.
- Pagination: A method of breaking large amounts of data into smaller, readable pages to improve system performance and user experience.
- Filtering: The ability to narrow down large datasets by specific attributes like date, product, or store location to find relevant information quickly.

1.4 Business Value

- Improved Accountability: By maintaining a clear history of stock movements, you can easily identify discrepancies and understand the reasons behind inventory fluctuations.
- Enhanced Reporting: The ability to filter by transaction type and date range allows managers to generate accurate reports on sales performance or stock replenishment trends.
-

Operational Efficiency: With quick access to historical data, staff can resolve inventory inquiries faster without needing to manually cross-reference multiple paper or digital logs.

- Better Decision Making: Having visibility into the net change of stock helps in planning future inventory needs and identifying stores that may require stock adjustments.

BUSINESS REQUIREMENTS DOCUMENT

Product History JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Product History feature provides a reliable audit trail for your inventory. It allows the system to track and retrieve a chronological record of changes made to any specific product. By capturing snapshots of pricing, status, and configuration settings whenever a change occurs, the system ensures you have a clear view of how a product's details have evolved over time.

1.2 Step-by-Step Flow

1. Request: The system receives a request to view the history of a specific product.
2. Query: The system searches the database for all recorded changes associated with that product ID.
3. Sort: The results are organized in reverse chronological order, ensuring the most recent updates appear first.
4. Format: The raw data is converted into a standardized, readable format (JSON) that includes all relevant details, such as who made the change, when it happened, and the specific price or status updates applied at that time.
5. Delivery: The formatted history list is returned to the user or application interface.

1.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific product.
- JSON Representation: A standardized, lightweight format used to structure data so that it can be easily read and shared between different parts of the software.
- Primary Key: A unique identifier for each specific history entry, ensuring that every change record is distinct and traceable.
- Pagination: The ability to limit the number of records returned at once (using "limit" and "offset"), which keeps the system fast and responsive even when a product has a long history of changes.

1.4 Business Value

- Accountability: By recording who updated a product and when, your team can easily identify the source of any configuration or pricing changes.
- Data Integrity: Having a historical record helps in troubleshooting discrepancies and provides a safety net if a product's settings need to be reverted to a previous state.
- Informed Decision Making: Access to historical pricing and status trends allows management to analyze past product performance and strategy shifts over time.

BUSINESS REQUIREMENTS DOCUMENT

Store Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Store feature provides a standardized way for the Lumi ERP system to manage and retrieve information about individual store locations. By defining a clear structure for store data, we ensure that every store record is consistent, reliable, and easily accessible across the platform.

1.2 Step-by-Step Flow

1. Data Definition: We establish a formal "Store Schema" that acts as a blueprint. This defines exactly what information must be included for every store (a unique ID, the store name, and a store code).
2. Data Retrieval: When the system needs to display a list of stores, it performs a targeted search of the database. It specifically requests the ID, name, and code for every store record found.
3. Standardization: The system takes the raw data retrieved from the database and maps it into a clean, uniform format.
4. Delivery: The final, organized list of stores is provided to the application, ensuring that the information matches the agreed-upon blueprint defined in the first step.

1.3 Key Concepts

- Schema: A set of rules or a "blueprint" that defines the required structure and format of data, ensuring consistency.
- Unique Identifier (UUID): A unique string of characters assigned to each store to ensure it can be distinguished from every other store in the system without error.
- Data Mapping: The process of taking information from our internal database and translating it into a standardized format that the rest of the software can easily understand and use.

1.4 Business Value

- Data Integrity: By enforcing a strict schema, we prevent incomplete or malformed store records from entering the system, which reduces errors in reporting and operations.
- System Reliability: Standardizing how store information is retrieved ensures that different parts of the ERP system can communicate effectively without needing custom adjustments for every new store added.
- Scalability: This structured approach allows the business to easily add or manage thousands of store locations while maintaining a predictable and high-performing user experience.

BUSINESS REQUIREMENTS DOCUMENT

Service Product Type Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Service Product Type feature allows the Lumi ERP system to categorize services consistently. By defining these types, the system ensures that every service is correctly linked to the appropriate accounting records, which automates financial tracking and tax reporting (specifically for PPh 23 refunds) whenever a service is performed.

1.2 Step-by-Step Flow

1. Definition: A new service category is created with a name, description, and links to specific accounting accounts.
2. Accounting Mapping: The system assigns a "Service Account" to the category to track revenue or costs in the general ledger, and optionally assigns a "Refund Account" for tax-related adjustments.
3. Activation: The category is marked as "active," making it immediately available for selection in service-related forms and dropdown menus.
4. Maintenance: Users can update existing categories or deactivate them if they are no longer in use, ensuring the system only shows relevant options.
5. Retrieval: When viewing service lists, the system automatically pulls the active categories and displays their associated accounting names for clarity.

1.3 Key Concepts

- Service Product Type: A classification label used to group similar services (e.g., "Maintenance," "Repair," or "Consulting") for better organization and reporting.
- Chart of Accounts (COA): The master list of financial accounts used by the business; this feature links service types to these accounts to ensure money is recorded in the right place.
- Service Account: The specific accounting entry that tracks the financial activity of a particular service type.
- Refund Account: A dedicated accounting entry used to manage specific tax refunds, such as PPh 23, associated with a service.
- Active Status: A toggle that controls whether a service type appears in the system's dropdown menus, allowing you to hide outdated categories without deleting their historical data.

1.4 Business Value

- Financial Accuracy: By mandating a link to the Chart of Accounts, the system eliminates manual data entry errors, ensuring that every service transaction is automatically mapped to the correct financial ledger.
- Streamlined Reporting: Categorizing services allows management to easily generate reports on which service types are performing best or incurring the most costs.
-

Tax Compliance: The built-in mapping for refund accounts simplifies the complex process of handling tax withholdings like PPh 23, reducing the risk of errors during tax season.

- Operational Efficiency: Standardizing service types ensures that all team members use consistent terminology, making the system easier to navigate and maintain.

BUSINESS REQUIREMENTS DOCUMENT

Service Product Tag Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Service Product Tag feature introduces a standardized way to categorize and label service products within the Lumi ERP system. By implementing a formal data structure, we ensure that every tag associated with a service is consistent, accurately tracked, and properly validated before it is saved to the system. This prevents data errors and ensures that the tagging system remains reliable for reporting and selection purposes.

1.2 Step-by-Step Flow

1. Data Entry: When a tag is created or updated, the system collects the necessary information, including the tag's name, its description, and its status (active or inactive).
2. Validation Check: The system automatically verifies that all mandatory information—specifically the unique tag ID, the associated service product ID, and the tag name—is present.
3. Format Verification: The system confirms that the data provided is in the correct format (e.g., ensuring IDs are numbers and names are text).
4. Status Assignment: The system checks the "active" status to determine if the tag should be available for selection in dropdown menus across the platform.
5. System Acceptance: If all checks pass, the tag is accepted and stored; if any required information is missing or formatted incorrectly, the system rejects the entry to maintain data integrity.

1.3 Key Concepts

- Service Product Tag: A label or category assigned to a specific service product to help with organization and filtering.
- Validation: An automated "quality check" that ensures data is complete and correctly formatted before it is processed by the system.
- Active Status: A toggle that controls whether a tag is currently visible and usable in the application, allowing you to "retire" old tags without deleting their history.
- Required Fields: Essential pieces of information (ID, Service ID, and Name) that must be provided for a tag to exist within the system.

1.4 Business Value

- Improved Data Accuracy: By enforcing strict validation rules, we eliminate "dirty data" and ensure that all service tags are correctly linked to their respective products.
- Operational Efficiency: Standardizing how tags are handled allows for smoother integration across the ERP, ensuring that dropdown menus and search filters always display reliable, up-to-date options.
-

Flexibility: The ability to toggle tags as "active" or "inactive" gives your team control over the tagging environment, allowing you to manage your service catalog as your business needs evolve without losing historical data.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Product Schedule Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Schedule Card is a display component on the Product Detail Page that provides clear visibility into a product's active lifecycle. It shows the specific date range during which a product schedule is considered valid, helping users quickly identify when a product's availability begins and ends.

1.2 Step-by-Step Flow

1. The system retrieves the "Valid From" and "Valid To" dates associated with the product schedule.
2. The component displays these dates in a clear, read-only format for the user to review.
3. The system automatically compares the two dates to ensure the schedule is logically sound.
4. If the "Valid To" date is earlier than the "Valid From" date, the system highlights the end date in red and displays a warning message to alert the user of the configuration error.

1.3 Key Concepts

- Valid From: The start date indicating when the product schedule becomes active.
- Valid To: The end date indicating when the product schedule expires.
- Validation Warning: A visual indicator that triggers if the schedule dates are set in an illogical order (i.e., the end date precedes the start date).

1.4 Business Value

This feature improves data integrity and operational efficiency by providing immediate feedback on product scheduling. By automatically flagging illogical date ranges, it prevents potential errors in product availability, allowing team members to quickly spot and address scheduling conflicts without needing to manually verify the timeline.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Company Pricing Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Company Pricing Card is a new feature on the Product Detail Page designed to provide internal staff with immediate visibility into the financial breakdown of a product. It displays the specific costs associated with purchasing the item from a supplier and the established wholesale pricing for customers, ensuring that key financial data is easily accessible while viewing product details.

1.2 Step-by-Step Flow

1. Data Retrieval: When a user opens a product page, the system automatically fetches the latest pricing information for that specific product.
2. Loading State: While the information is being retrieved, a temporary loading indicator is displayed to the user.
3. Displaying Supply Costs: Once loaded, the card displays the "Company Supply Price," which represents the amount the company pays the supplier, inclusive of tax.
4. Displaying Wholesale Pricing: The card also displays the "Wholesale Price," showing the base sale price for wholesale customers alongside the final amount including tax.
5. Error Handling: If the system is unable to retrieve the pricing data, an error message is displayed to inform the user that the information is currently unavailable.

1.3 Key Concepts

- Company Supply Price: The cost the company incurs when purchasing the product from a supplier; this figure includes applicable taxes.
- Wholesale Price: The price at which the product is sold to wholesale customers, presented both as a base price and a tax-inclusive total.
- Read-Only View: The pricing information is presented for informational purposes only and cannot be edited directly from this view.
- Help Tooltips: Small interactive icons located next to price labels that provide quick definitions to ensure clarity on what each cost represents.

1.4 Business Value

This feature improves operational efficiency by eliminating the need for staff to navigate to separate financial reports or spreadsheets to find product costs. By surfacing this data directly on the Product Detail Page, team members can make faster, more informed decisions regarding wholesale strategy and procurement, while maintaining a clear understanding of the company's profit margins and tax obligations.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Dimensions Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Dimensions Card is a new component for the Lumi ERP product detail page. Its purpose is to provide a clear, at-a-glance view of a product's physical specifications—specifically its volume and weight. This ensures that users have immediate access to essential logistical information directly within the product profile.

1.2 Step-by-Step Flow

1. Data Retrieval: The system automatically pulls the specific volume and weight information associated with the product currently being viewed.
2. Validation: The system checks if the information is available. If the data is missing or incomplete, the system will display "N/A" instead of leaving a blank space, ensuring the page remains clean and professional.
3. Display: The validated information is presented in a dedicated section on the product page, clearly labeled as "Volume (Mililiter)" and "Weight (Gram)."

1.3 Key Concepts

- Read-Only Fields: Information that is displayed for reference purposes only and cannot be edited directly from this view.
- Data Consistency: A standard approach to handling missing information by displaying "N/A," which prevents layout errors and provides a better user experience.
- Product Detail Context: The specific area of the ERP where users view comprehensive information about a single product.

1.4 Business Value

- Improved Decision Making: By surfacing physical dimensions directly on the product page, staff can quickly verify if a product meets shipping or storage requirements without needing to consult external documents.
- Enhanced Data Integrity: The use of standardized labels and consistent "N/A" placeholders ensures that the product page remains professional and easy to read, even when certain data points are not yet available in the system.
- Operational Efficiency: Reducing the time spent searching for basic product specifications helps streamline warehouse and logistics workflows.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Settings Card is a new component on the Product Detail Page that provides a quick, read-only summary of a product's configuration. It allows users to instantly verify the operational status of a product—such as whether it is currently active, available for ordering, or restricted—without needing to navigate through complex menus or edit screens.

1.2 Step-by-Step Flow

1. Data Retrieval: When you open a product page, the system automatically fetches the latest configuration settings for that specific item.
2. Loading State: While the information is being retrieved, a temporary placeholder (skeleton loader) is displayed to ensure a smooth visual experience.
3. Displaying Status: Once the data is loaded, the card displays a list of key settings. Each setting is accompanied by a visual indicator: a green checkmark for "enabled" (active) or a red cross for "disabled" (inactive).
4. Contextual Guidance: For settings that require more clarity, a help icon is provided. Hovering over these icons reveals a brief explanation of what that specific setting does.

1.3 Key Concepts

- Read-Only View: This component is for informational purposes only; it allows you to see the current status of a product but does not allow you to change these settings directly from this card.
- Status Indicators: Simple visual cues (green checkmarks and red crosses) that allow for immediate identification of a product's configuration state.
- Help Tooltips: Small, informative pop-ups that provide additional context for specific settings, helping users understand the impact of features like "Product Freeze" or "Can Order."

1.4 Business Value

- Improved Efficiency: Users can verify product configurations at a glance, reducing the time spent searching for details in other parts of the system.
- Reduced Errors: By clearly displaying whether a product is "Active" or "Frozen," staff can avoid mistakes during the ordering or transfer process.
- Enhanced Transparency: Providing clear, accessible definitions for complex settings (like "Product Freeze") ensures that all team members understand the operational constraints of a product, leading to more consistent inventory management.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Attributes Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Attributes Card is a dedicated section on the product detail page designed to provide a clear, organized summary of a product's classification and specific technical details. This component acts as a "read-only" information panel, ensuring that users can quickly identify key metadata about an item without the need for editing or complex navigation.

1.2 Step-by-Step Flow

1. The system retrieves the product information from the central database.
2. The "Unit Bisnis" (Business Unit) is displayed to identify the product's organizational origin.
3. The "Kategori Item" (Item Category) is shown to clarify the product type.
4. The "Tipe Mobil" (Car Type) is displayed to indicate compatibility or vehicle application.
5. Three additional custom attribute slots (Attribute 4, Attribute 5, and Attribute 6) are populated to show any remaining specific metadata associated with the product.
6. All information is presented in a clean, static list format for easy viewing.

1.3 Key Concepts

- Read-only: Information is displayed for reference purposes only and cannot be modified directly within this view.
- Metadata: Descriptive data about the product, such as its category or business unit, which helps in organizing and identifying items.
- Custom Attribute Slots: Flexible fields that allow the system to display specific product details that may vary depending on the item type.

1.4 Business Value

This feature improves operational efficiency by providing staff with immediate access to critical product specifications. By centralizing this information on the product page, users spend less time searching for details in external documents or secondary systems, reducing the risk of errors during product identification and ensuring consistent information across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Changes Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Changes Card" is a new feature on the Product Detail Page that provides a clear, read-only history of a product record. It acts as an audit trail, allowing users to see exactly when a product was first created and the details of its most recent modification. This ensures transparency and accountability for all changes made to product data within the Lumi ERP system.

1.2 Step-by-Step Flow

1. When a user opens a specific product page, the system automatically retrieves the audit history for that item.
2. The system displays the original creation date and time of the product record.
3. The system displays the date and time of the most recent update to the record.
4. The system identifies the specific user who performed the last update and notes the type of action they took (such as an edit or update).

1.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific product.
- Read-Only: Information that is displayed for viewing purposes only and cannot be modified by the user.
- Action Type: A label indicating the nature of the change made to the record, providing context for why the update occurred.

1.4 Business Value

This feature improves data governance and operational transparency. By providing a clear history of who changed what and when, teams can easily track the lifecycle of a product, resolve discrepancies faster, and maintain a reliable record of truth for all product-related information.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Menu

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Product Detail Menu is a navigation component designed to help users easily switch between different views related to a specific product. It acts as a central hub, allowing users to toggle between product information, historical data, and stock levels across various locations (warehouses and stores) without leaving the product context.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically detects the current URL to determine which menu item should be highlighted. If no specific section is identified, it defaults to the "Product" view.
2. User Interaction: The user selects a menu item (e.g., "Warehouse Stocks" or "Product History") from the navigation list.
3. State Update: Upon clicking, the system updates the menu to mark the selected item as "active," providing visual feedback to the user.
4. Navigation: The application immediately redirects the user to the specific page associated with that menu item.
5. Visual Feedback: The active menu item is highlighted with a distinct underline and bold text, ensuring the user always knows which section they are currently viewing.

1.3 Key Concepts

- Active Tab State: A feature that tracks which menu item is currently selected, ensuring the user has a clear visual indicator of their location within the application.
- Navigation Routing: The underlying mechanism that maps each menu label to a specific page or data view within the ERP system.
- Default State: A safety feature that ensures the "Product" view is always selected if the user arrives at the page without a specific sub-section defined.

1.4 Business Value

- Improved User Experience: By providing a consistent and intuitive navigation bar, users can move between complex product data sets quickly and efficiently.
- Reduced Cognitive Load: The clear visual highlighting of the "active" tab helps users maintain context, reducing the likelihood of confusion when navigating between similar-looking data pages.
- Streamlined Workflow: This component centralizes access to critical information—such as stock levels and historical trends—allowing staff to perform inventory and product analysis tasks with fewer clicks.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Tax Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Tax Card is a new component on the Product Detail Page designed to provide a clear, at-a-glance view of tax-related information for a specific product. This feature ensures that essential tax data is easily accessible to users while maintaining a clean, read-only format that prevents accidental changes to sensitive financial information.

1.2 Step-by-Step Flow

1. The system retrieves the product information from the database.
2. The Tax Card component identifies the specific tax details associated with that product.
3. The system displays the Tax rate (e.g., PPN), the Tax Product Code, and the Tax Unit of Measure in a dedicated section on the page.
4. If any specific piece of information is missing for a product, the system will display "N/A" to ensure the user knows the data is unavailable rather than simply blank.
5. The information is presented in a read-only format, ensuring users can view the data without the ability to edit it directly from this screen.

1.3 Key Concepts

- Read-only: A display setting that allows users to view information without the ability to modify or delete it, ensuring data integrity.
- Tax Product Code: A specific identifier used to categorize the product for tax reporting and invoicing purposes.
- Tax Unit of Measure: The standard unit used to calculate or report tax for the product (e.g., per item, per weight, etc.).
- Data Placeholder: A default label (N/A) used to maintain a consistent layout when specific product information is not currently available in the system.

1.4 Business Value

This feature improves operational transparency by centralizing critical tax information directly on the product page. By providing a clear, read-only view, it reduces the risk of manual errors during data entry and ensures that staff have immediate access to the correct tax codes and rates required for accurate invoicing and regulatory compliance.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Details Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Details Card is a clean, read-only summary component designed for the product page. It provides a centralized view of a product's core identity, ensuring that essential information—such as codes, branding, and descriptions—is easily accessible to users without the risk of accidental modification.

1.2 Step-by-Step Flow

1. Header Display: The card prominently displays the full product name at the top.
2. Categorization: The system shows the product's Type and Brand, combining both the internal code and the descriptive name for clarity.
3. Identification: The card lists the internal SKU, a unique Product Code, and the specific Supplier Product Code.
4. Quick Copy: A dedicated button is provided next to the SKU, allowing users to instantly copy the number to their clipboard for use in other systems.
5. Sourcing: The system displays the list of authorized suppliers, defaulting to "All Suppliers" if no specific restrictions are set.
6. Contextual Details: The card presents a descriptive text block and any relevant tags associated with the product to provide further context.

1.3 Key Concepts

- Read-Only Fields: Information is presented for viewing purposes only; users cannot edit these fields directly within this component.
- Identity Fields: The core data points (SKU, Product Code, etc.) that uniquely identify a product within the ERP system.
- Copy-to-Clipboard: A utility feature that improves efficiency by allowing users to grab the SKU with a single click, reducing manual entry errors.
- Tag Pills: A visual way to display product labels or categories, which remain hidden if no tags are assigned to the product.

1.4 Business Value

- Data Integrity: By making these fields read-only, the system prevents accidental changes to critical product identity data.
- Operational Efficiency: The "Copy to Clipboard" feature streamlines workflows, especially when users need to move SKU data into external shipping or procurement tools.
- Improved User Experience: Consolidating fragmented product information into a single, organized card reduces the time users spend searching for basic product details.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Store Pricing Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Store Pricing Card is a dedicated section on the product detail page designed to provide clear, at-a-glance financial information for store managers. It displays the essential costs and pricing associated with a specific product, ensuring that both the purchase cost and the final selling price are transparent and easy to reference.

1.2 Step-by-Step Flow

1. Data Retrieval: The system fetches the specific pricing data for the selected product.
2. Displaying Supply Price: The card shows the "Supply Price," which represents the cost the store pays to acquire the product. A help icon is provided to clarify that this figure includes tax.
3. Displaying Retail Price: The card shows the "Retail Price," which is the price at which the product is sold to customers.
4. Displaying Tax Details: Alongside the retail price, the system automatically displays the tax-inclusive amount, ensuring the user understands the final cost structure.
5. Formatting: All financial figures are automatically formatted as Indonesian Rupiah (IDR) for consistency and readability.

1.3 Key Concepts

- Supply Price: The cost price of the product from the store's perspective, inclusive of taxes.
- Retail Price: The final price set for the product to be sold to the end customer.
- Tax-Inclusive Amount: The total price of the product after all applicable taxes have been added, displayed alongside the retail price for clarity.
- Read-Only Fields: These values are for informational purposes only and cannot be edited directly within this specific component.

1.4 Business Value

This feature improves operational efficiency by centralizing critical financial data directly on the product page. By clearly separating the store's acquisition cost from the customer's retail price, store managers can quickly assess profit margins and verify pricing accuracy without needing to navigate to separate financial reports or spreadsheets.

BUSINESS REQUIREMENTS DOCUMENT

Product Detail Page - Tracking and Bundle Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product Detail Page now includes a "Product Configuration" card. This component provides a quick, at-a-glance summary of how a specific product is set up within the Lumi ERP system. It uses clear visual indicators to show whether stock tracking is active and whether the item is categorized as a bundle or a flexible bundle.

1.2 Step-by-Step Flow

1. Data Retrieval: When a user views a product page, the system automatically fetches the product's configuration details from the database.
2. Stock Tracking Display: The system checks if stock tracking is enabled. A green checkmark appears if it is active, and a red cross appears if it is disabled. A help icon is provided to explain that enabling this feature allows the system to automatically reduce inventory levels during sales.
3. Flexible Bundle Status: The system checks if the product is configured as a "flexible bundle." A green checkmark or red cross is displayed to indicate the current status.
4. Bundle Status: The system checks if the product is categorized as a standard bundle. A green checkmark or red cross is displayed to indicate the current status.

1.3 Key Concepts

- Stock Tracking: A setting that determines if the system should automatically update inventory counts when a sale occurs.
- Bundle: A product configuration where multiple items are grouped together and sold as a single unit.
- Flexible Bundle: A specific type of bundle that allows for more customizable options or selections within the group.
- Read-Only Status: These indicators are for informational purposes only; they allow users to verify the product's configuration without needing to edit the settings.

1.4 Business Value

This feature improves operational transparency by allowing staff to instantly verify product settings without navigating through complex administrative menus. By clearly displaying whether stock tracking is enabled, it helps prevent inventory errors—ensuring that physical goods are tracked correctly while services remain unaffected. Additionally, the clear labeling of bundle types helps sales and support teams quickly identify how a product is structured, leading to faster customer service and more accurate order processing.

BUSINESS REQUIREMENTS DOCUMENT

Product

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Product feature serves as the central foundation for the Lumi ERP system. It acts as a master directory for all items, managing their identity, classification, pricing, and inventory status. By linking products to specific brands, types, and locations (stores and warehouses), the system ensures that every item can be tracked accurately from purchase through to final sale.

1.2 Step-by-Step Flow

1. Classification: Every product is assigned a specific brand and type to keep the catalog organized and searchable.
2. Definition: Core details—such as SKU, name, pricing, and business unit—are established in the central product directory.
3. Customization: The system allows for flexible labeling of product attributes (like category or car type) to match your company's specific terminology.
4. Inventory Tracking: Stock levels are monitored separately for stores and warehouses, with dedicated history logs that record every movement (such as sales or deliveries).
5. Pricing & Audit: The system tracks price changes and purchase history, ensuring there is a clear record of how much an item cost and how it has been priced over time.
6. Voucher Management: Special items, such as vouchers, are managed with their own set of rules regarding validity, redemption locations, and expiration dates.

1.3 Key Concepts

- Product Directory: The main database table that holds all essential information about an item, acting as the "single source of truth."
- Inventory Tracking: The process of monitoring how many units of a product are available at specific physical locations (stores or warehouses).
- Stock History: A digital audit trail that records every time a product's quantity changes, including the reason for the change (e.g., a sale or a new delivery).
- Pricing Overrides: The ability to set different prices for the same product depending on the context, such as the specific store, region, or customer group.
- Custom Attributes: Flexible fields that allow you to categorize products using your own business terminology without needing a system redesign.
- Vouchers: A specialized product type that includes unique rules for validity periods and where they can be issued or redeemed.

1.4 Business Value

- Operational Accuracy: By centralizing product data and inventory, you reduce the risk of errors in stock counts and pricing across different locations.
- Better Decision Making: With detailed history logs for both stock and pricing, you can easily analyze sales trends and purchase patterns to optimize your inventory levels.
- Flexibility: The system adapts to your business needs through custom attributes and location-based pricing, allowing you to scale or change your product strategy without technical friction.
- Audit Readiness: Comprehensive history tables provide a clear, transparent record of all transactions, making it easier to manage reporting and compliance.

BUSINESS REQUIREMENTS DOCUMENT

Setup

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Setup module provides the foundational configuration for the Lumi ERP system. It allows administrators to manage essential business data, including warehouse locations, company profile details, administrative regions, and payment methods. This module ensures that the system is correctly tailored to the company's specific operational needs and geographic requirements.

1.2 Step-by-Step Flow

1. Company Profile Setup: Administrators define core company information, such as business name, address, currency, and time zone. This section also handles platform-wide settings and document tracking (e.g., invoice numbering formats).
2. Warehouse Management: Users can create and maintain a list of warehouses. Each warehouse is assigned a unique code and location details, which are essential for inventory tracking.
3. Administrative Region Configuration: The system maintains a hierarchical list of administrative areas (Province, Regency, District, and Village) to support standardized location data across the platform.
4. Payment Type Configuration: The system provides a master list of available payment methods (e.g., Cash, Credit/Debit Cards, QRIS).
5. Store-Level Payment Mapping: Administrators can control which payment methods are active at specific store locations. The system automatically manages these mappings to ensure that each store only offers the payment options enabled for it.

1.3 Key Concepts

- Company Profile: The central repository for business identity and operational settings, including tax identifiers and regional preferences.
- Warehouse: A physical or logical location where inventory is stored, identified by a unique code for easy tracking.
- Administrative Area: A structured, hierarchical list of regions used to ensure consistent location data entry throughout the system.
- Payment Type: A defined method of transaction (e.g., Cash or specific Bank Transfer) available for use within the business.
- Payment Mapping: A configuration that links specific payment types to individual stores, allowing businesses to toggle payment availability on or off per location.

1.4 Business Value

-

Operational Consistency: By centralizing company and warehouse data, the system ensures that all departments use the same standardized information.

- Flexibility: The ability to map payment types to specific stores allows businesses to customize their checkout experience based on the capabilities or requirements of individual locations.
- Scalability: The structured approach to administrative regions and document tracking allows the system to grow alongside the business, supporting new locations and complex operational requirements without manual data entry errors.
- Auditability: Every record includes tracking for who created or updated the information, providing a clear history of configuration changes for compliance and management oversight.

BUSINESS REQUIREMENTS DOCUMENT

User

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The User Management feature provides a secure foundation for handling staff access within the Lumi ERP. It is designed to manage user identities, control active login sessions, track security-related events, and protect the system against unauthorized access attempts. By separating user data from session and security logs, the system ensures that account information remains protected while providing a clear trail of activity for administrative oversight.

1.2 Step-by-Step Flow

1. Registration & Identity: When a user is created, their profile is stored with a secure password hash and a specific role (e.g., Admin, Staff). The system ensures email addresses are unique and case-insensitive.
2. Login Attempt: Every time someone tries to sign in, the system records the attempt in a dedicated log. This allows the system to detect suspicious patterns, such as repeated failed logins from a single IP address or against a specific account.
3. Authentication & Session: Upon a successful login, the system creates a secure session. This session acts as a "digital key" that allows the user to stay logged in for a set period without re-entering their credentials.
4. Security Monitoring: Throughout the user's lifecycle, the system records significant actions (like password changes or role updates) in an audit log. This creates an immutable history of who did what and when, which is essential for security compliance.
5. Access Control: If a user is deactivated or a security event occurs, the system can immediately revoke all active sessions, ensuring that the user can no longer access the ERP.

1.3 Key Concepts

- User Profile: The core record containing identity information, account status (active/inactive), and security flags (such as a requirement to change a password upon next login).
- Session Management: A secure mechanism that tracks active users. It includes "sliding expiration," meaning sessions stay active while the user is working but expire automatically after a period of inactivity.
- Audit Trail: A permanent, read-only record of security-sensitive actions. It provides accountability by linking actions to specific users and recording the context of those changes.
- Login Throttling: A security measure that monitors login attempts to prevent "brute force" attacks, where an unauthorized party tries to guess a password by repeatedly attempting to sign in.
- Role-Based Access: The system assigns roles to users, which determines their level of authority and what they can do within the ERP.

1.4 Business Value

- Enhanced Security: By tracking login attempts and maintaining an audit log, the system proactively defends against unauthorized access and provides clear visibility into system activity.
- Operational Control: Administrators can easily manage staff access, including the ability to lock accounts or force password resets, ensuring that only authorized personnel have access to sensitive business data.
- Compliance & Accountability: The audit trail ensures that all critical changes are documented, which is vital for internal oversight and meeting business compliance standards.
- Reliability: The session management system ensures that users have a smooth, uninterrupted experience while maintaining strict security standards for how long a user remains logged in.

BUSINESS REQUIREMENTS DOCUMENT

Voucher

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Voucher feature provides a structured way to define and manage digital vouchers within the Lumi ERP system. By linking each voucher to a specific product, the system ensures that vouchers are treated as distinct items with clear pricing, validity periods, and usage rules. This feature allows businesses to control where vouchers can be sold and redeemed, providing flexibility for both company-wide promotions and location-specific campaigns.

1.2 Step-by-Step Flow

1. Voucher Definition: A new voucher is created and linked to a specific product. During this setup, you define its type (e.g., standard or flexible), its monetary value, and its pricing rules (such as whether the price is fixed or can be set at the time of sale).
2. Setting Scope: You determine the "scope" for the voucher, which dictates where it can be sold and where it can be redeemed. You can choose to make these actions available at "all" stores or restrict them to "specific" stores.
3. Location Mapping: If you select "specific" for either selling or redeeming, the system uses dedicated tables to map the voucher to the authorized store locations.
4. Validation & Status: You set the validity period (start and end dates) and the current status (e.g., active or expired). The system automatically tracks who created or updated the voucher for audit purposes.
5. Usage: When a transaction occurs, the system checks the voucher's status, validity dates, and location permissions to ensure the voucher is eligible for the current store and customer.

1.3 Key Concepts

- Voucher: A digital asset linked to a product that holds a specific monetary value and set of usage rules.
- Scope: A setting that defines whether a voucher is valid globally (all stores) or restricted to a subset of locations (specific stores).
- Open Price: A setting that allows staff to manually enter the selling price of a voucher at the time of purchase, rather than using a pre-set price.
- Audit Trail: Automatic tracking of which user created or modified a voucher record, ensuring accountability.
- Validity Period: The timeframe during which a voucher is active and eligible for use, managed by start and end dates or duration-based expiry.

1.4 Business Value

- Operational Control: Businesses can precisely manage where vouchers are issued and redeemed, preventing unauthorized usage and ensuring promotions are targeted correctly.
-

Flexibility: The "open price" and "flexible" voucher types allow for dynamic pricing strategies, such as gift cards or custom-value vouchers, without needing to create new product records for every variation.

- Data Integrity: By linking vouchers to existing products, the system maintains consistent reporting and inventory tracking across the ERP.
- Compliance & Security: Built-in audit trails and status management ensure that voucher usage is transparent and that expired or inactive vouchers cannot be misused.

BUSINESS REQUIREMENTS DOCUMENT

Customer

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Customer feature provides a robust database structure for managing customer information within the Lumi ERP system. It is designed to handle various customer types—including retail, wholesale, franchise, and consignment—while supporting complex business requirements like credit limits, tax information, and custom pricing. The system is built to remain fast and responsive even as the number of customer records grows.

1.2 Step-by-Step Flow

1. Customer Creation: A new customer record is created, capturing essential details such as name, contact information, and business type (e.g., wholesale or retail).
2. Profile Enrichment: Additional details are linked to the customer, including multiple addresses (shipping/billing), membership program enrollments, and specific occupation data.
3. Financial Setup: Financial parameters are configured, such as credit limits, payment terms, and specific accounting accounts (e.g., for deposits or receivables).
4. Operational Management: The system tracks ongoing interactions, such as sales history, product-specific pricing overrides, and any post-sale claims or returns.
5. Data Maintenance: The system automatically updates timestamps and maintains accurate counts (like the number of customers in a specific group) to ensure data integrity without manual intervention.

1.3 Key Concepts

- Customer Entity: The central record containing core identity and contact information for an individual or business.
- Sub-Entities: Related data tables that extend the customer profile, such as addresses, billing profiles, and membership details.
- Keyset Pagination: A high-performance method for browsing long lists of customers that ensures the system stays fast as the database grows.
- Trigram GIN Index: A specialized search technology that allows the system to quickly find customers even if you only type a partial name or a "contains" search.
- Sanitized Phone: A system-generated field that strips formatting from phone numbers, ensuring that searches for a phone number are always accurate regardless of how the number was originally typed.
- Atomic Transactions: A safety feature that ensures when you save a customer and their related details (like addresses), the entire update succeeds or fails as one unit, preventing data inconsistencies.

1.4 Business Value

-

Scalability: By using advanced indexing and efficient pagination, the system ensures that searching and listing customers remains instantaneous, even with thousands of records.

- Data Accuracy: Automated triggers and generated fields (like the sanitized phone number) reduce human error and ensure consistent data quality across the organization.
- Flexibility: The schema supports diverse business models, allowing the same system to manage simple retail customers alongside complex wholesale or franchise accounts with specific pricing and credit rules.
- Operational Efficiency: By centralizing billing, address, and financial data, staff can access a complete 360-degree view of a customer from a single location, speeding up service and administrative tasks.

BUSINESS REQUIREMENTS DOCUMENT

Service Product

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Service Product feature provides a structured way to manage non-physical offerings (services) within the Lumi ERP system. It allows your team to define specific services, categorize them for accounting purposes, manage complex tax requirements, and track estimated service durations. This ensures that services are priced accurately, taxed correctly, and easily reportable for financial and operational analysis.

1.2 Step-by-Step Flow

1. Categorization: Every service is assigned a "Service Product Type." This classification links the service to specific accounting journals and refund accounts (such as PPh 23), ensuring that financial data is automatically routed to the correct ledgers.
2. Service Definition: You define the core details of the service, including a unique SKU, name, and description.
3. Pricing and Tax Configuration: You set the base price and configure tax details. The system supports both primary and secondary taxes, allowing you to specify whether the price includes tax or if it should be calculated separately.
4. Operational Settings: You can set an estimated time for the service. If a service price or duration varies by customer or situation, you can enable "Open" settings, which allow staff to manually enter the price or time at the moment of the transaction.
5. Reporting and Tagging: You can assign tags to services to group them for easier searching or reporting. Additionally, you can link services to specific tax units of measure and product codes to ensure compliance with official reporting requirements like e-Faktur.

1.3 Key Concepts

- Service Product Type: A category that dictates the accounting behavior of a service, such as which financial accounts are impacted when the service is sold or refunded.
- Open Price/Time: A setting that allows flexibility during a transaction, enabling staff to override default values when a service is customized or varies in duration.
- Tax Unit of Measure (UoM): A standardized list of 39 units (e.g., hours, minutes, units) used to ensure consistent tax reporting and measurement across all service types.
- Service Product Tags: Labels used to organize and filter services, making it easier to manage large catalogs of offerings.
- Including Tax: A configuration toggle that determines if the displayed price already accounts for tax, which automatically adjusts the underlying base price calculation.

1.4 Business Value

- Financial Accuracy: By linking services to specific accounting and refund accounts, you reduce manual data entry errors and ensure that tax liabilities are calculated and recorded correctly.
- Operational Efficiency: The ability to set estimated times helps with scheduling and resource planning, while "Open" fields provide the flexibility needed for dynamic service environments.
- Regulatory Compliance: Built-in support for tax product codes and standardized units of measure ensures that your business remains compliant with local tax reporting requirements (e-Faktur).
- Better Insights: Categorization and tagging allow management to generate detailed reports on service performance, helping you identify which service types are most profitable or frequently requested.

BUSINESS REQUIREMENTS DOCUMENT

Inventory

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Inventory feature for the Lumi ERP project provides a reliable way to track stock levels and movements between warehouses and stores. It ensures that whenever stock is moved or adjusted, the system automatically updates the current inventory counts and maintains a detailed audit trail of these changes. This system is designed to be "atomic," meaning that all related updates—such as changing a stock level and recording the history—happen together as a single, inseparable action. If any part of the process fails, the entire operation is cancelled to prevent data errors.

1.2 Step-by-Step Flow

The system handles inventory changes through two primary processes:

1. Stock Order Movements:

* When sending stock: The system decreases the quantity in the source warehouse and creates a history record to document the departure.
* When receiving stock: The system increases the quantity in the destination store and creates a history record to document the arrival.
* Consistency: These updates are bundled with the workflow status change (e.g., moving from "sent" to "received") to ensure the inventory always matches the order status.

2. Stock Adjustments (Stock Opname):

* When a physical count is performed, the system calculates the difference (variance) between the counted quantity and the system's recorded quantity.
* If a difference exists, the system updates the store's stock level to match the physical count.
* A history record is created to explain the adjustment, ensuring there is a clear audit trail for why the stock level changed.

1.3 Key Concepts

- Atomic Transaction: A safety feature that ensures a group of database changes either all succeed together or all fail together, preventing partial or corrupted data.
- Stock History: A permanent, append-only log that tracks every movement or adjustment of inventory, providing a clear audit trail for accountability.
- Variance: The difference between the expected stock (what the system thinks is there) and the actual stock (what was physically counted).
-

Workflow State: The current status of an order or adjustment (e.g., "draft," "sent," "received," or "completed"), which triggers the corresponding inventory updates.

1.4 Business Value

- Data Accuracy: By automating inventory updates, the system eliminates manual calculation errors and ensures that stock levels are always up-to-date.
- Auditability: Every change to inventory is logged with a reference code, making it easy to trace stock movements and investigate discrepancies.
- Operational Reliability: The use of atomic transactions prevents "ghost" inventory or mismatched records, ensuring that the business can trust the data when making purchasing or sales decisions.
- Process Integrity: By linking inventory movements directly to workflow states, the system ensures that stock is only deducted or added when the business process (like shipping or receiving) is officially confirmed.

BUSINESS REQUIREMENTS DOCUMENT

Finance

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature establishes the foundational "Master Data" for the Finance module within the Lumi ERP system. By creating standardized lists for taxes, accounting structures, and product classifications, the system ensures that financial data is consistent, accurate, and compliant with reporting requirements (such as e-Faktur). These tables act as the "source of truth" that powers dropdown menus and selection fields across the entire application.

1.2 Step-by-Step Flow

1. Tax Product Classification: The system maintains a list of official tax codes used to categorize goods and services, ensuring that every product is correctly identified for tax reporting.
2. Chart of Accounts (COA) Management: The system organizes the company's financial accounts into a structured tree, allowing for clear categorization of assets, liabilities, and expenses.
3. Pricelist Configuration: The system stores various pricing strategies, allowing the business to define and select specific price lists (e.g., wholesale vs. retail) for different company operations.
4. Tax Rate Definition: The system manages specific tax rates (like VAT/PPN), allowing users to define and apply the correct tax percentages to financial transactions.
5. Unit of Measure (UoM) Standardization: The system provides a standardized list of measurement units (e.g., Kilograms, Pieces) to ensure consistency when calculating taxes and inventory values.

1.3 Key Concepts

- Master Data: The core, essential information used across the ERP to ensure that everyone is using the same definitions for taxes, accounts, and units.
- Company-Scoped Data: Financial information (like the Chart of Accounts or Tax rates) that is specific to a particular business entity, ensuring data privacy and organizational separation.
- Postable Account: A specific type of account in the Chart of Accounts that is eligible to receive direct financial entries, as opposed to "parent" accounts which are used only for grouping.
- Tax Product Code: A standardized identifier required for regulatory compliance, specifically for mapping items to their correct tax treatment in e-Faktur.
- Hierarchy (Tree Structure): The ability to link accounts to a "parent" account, which helps in generating organized financial reports and summaries.

1.4 Business Value

- Regulatory Compliance: By using standardized Tax Product Codes and defined tax rates, the business can automate accurate tax reporting and meet local government requirements (e-Faktur) with minimal manual effort.

- Operational Consistency: Centralizing data like Units of Measure and Pricelists prevents errors caused by inconsistent naming or manual entry, ensuring that sales and accounting teams are always aligned.
- Scalability: The company-scoped architecture allows the ERP to support multiple business entities within the same system while keeping their financial structures distinct and organized.
- Improved Reporting: A well-structured Chart of Accounts enables faster, more accurate financial analysis and easier generation of balance sheets and income statements.

BUSINESS REQUIREMENTS DOCUMENT

Service

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Service feature in the Lumi ERP system provides a structured way to manage workshop activities. It uses two primary documents to track the lifecycle of a service request: the Service Order (the high-level administrative record) and the Service Work Order (the operational document used by mechanics to perform the actual work). Together, these tables ensure that every service job is properly documented, linked to the correct customer and vehicle, and tracked through its various stages of completion.

1.2 Step-by-Step Flow

1. Initiation: A Service Order is created to act as the master record for a customer's request. This includes details like the type of service, the assigned advisor, and the vehicle involved.
2. Operational Planning: A Service Work Order is generated to serve as the specific job card for the workshop. This document tracks the progress of the work, from initial scheduling to final completion.
3. Linking: The Service Work Order is linked back to the original Service Order, ensuring that administrative and operational data remain synchronized.
4. Inventory Integration: If the work requires parts that are not currently in stock at the local store, the system identifies the shortfall and can automatically trigger a request for those parts from a central warehouse.
5. Status Tracking: Throughout the process, both documents are updated to reflect their current status (e.g., draft, in-progress, or completed), allowing managers to monitor the status of any job at a glance.

1.3 Key Concepts

- Service Order: The primary administrative header that captures the "big picture" of a service request, including financial totals, tax information, and customer details.
- Service Work Order: The detailed, day-to-day operational document that mechanics use to perform tasks on a vehicle.
- Reference Code: A unique, system-generated identifier for every order and work order, ensuring that every job can be easily tracked and audited.
- Status/State: A tracking mechanism that defines where a job is in its lifecycle (e.g., waiting, in-progress, or completed), which helps in managing workflow and reporting.
- Stock Order Integration: A smart feature that automatically detects when parts are missing for a job and initiates a request to replenish inventory, preventing delays in service.

1.4 Business Value

-

Improved Operational Efficiency: By separating the administrative "Service Order" from the mechanical "Work Order," the system allows office staff and workshop technicians to focus on their respective tasks without data clutter.

- Better Inventory Control: The automated link between missing parts and stock requests reduces manual effort and minimizes the risk of service delays caused by unavailable spare parts.
- Enhanced Accuracy: Centralizing data like vehicle history, odometer readings, and service status reduces human error and provides a reliable audit trail for every vehicle serviced.
- Streamlined Workflow: Real-time status tracking ensures that service advisors and managers always know the exact progress of a job, leading to better communication with customers and more predictable workshop turnaround times.

BUSINESS REQUIREMENTS DOCUMENT

Supplier

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Supplier feature provides a centralized database structure for managing business relationships with suppliers within the Lumi ERP system. It acts as the "source of truth" for supplier information, including contact details, financial terms, and specific operational settings. The system is designed to handle various types of suppliers—including standard, internal, and consignment-based partners—while maintaining a clear audit trail of changes and financial movements.

1.2 Step-by-Step Flow

1. Supplier Registration: A new supplier is created with essential details such as name, contact information, and financial settings (like credit limits and payment terms).
2. Operational Categorization: The system flags the supplier based on their role (e.g., internal vs. external, or consignment-based) to ensure they appear in the correct filtered lists and are handled correctly by the system's purchasing logic.
3. Product Mapping: Specific products are linked to the supplier, allowing the system to track unique discount rates and pricing terms for each item provided by that supplier.
4. Financial Tracking: If the supplier requires deposits, the system tracks the balance and records every transaction (payments made or deposits consumed) in a dedicated ledger.
5. Audit & History: Every time a supplier's core information (like address or credit terms) is updated, the system automatically saves a snapshot of the previous details to a history log, ensuring full accountability.

1.3 Key Concepts

- Supplier: The primary record representing a business entity that provides goods or services.
- Internal Supplier: A special category for intra-group suppliers that are managed within the same organization.
- Consignment: A business model where goods are held by the company but only paid for once they are sold; the system tracks these suppliers separately to manage "Consignment Closure."
- Supplier Deposit: A financial balance held with a supplier, used to manage prepayments or down payments.
- Product Mapping: A link between a supplier and a product that defines specific purchasing terms, such as discount rates.
- Audit History: A secure, read-only log that tracks changes to supplier details over time for compliance and reporting.

1.4 Business Value

- Operational Efficiency: By centralizing supplier data, the system ensures that purchasing teams always have access to accurate contact, tax, and financial information, reducing manual errors.
- Financial Control: Automated tracking of credit limits, payment terms, and deposit balances helps the finance team manage cash flow and prevent over-purchasing.
- Regulatory Compliance: The built-in audit history provides a clear record of who changed supplier information and when, which is essential for internal audits and transparency.
- Flexible Purchasing: The ability to distinguish between standard and consignment suppliers allows the business to automate complex accounting processes, such as calculating payments only when consignment stock is sold.

Sales

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Sales module in the Lumi ERP system is designed to manage the entire lifecycle of a sale, from the initial price offer to the final payment. It supports two primary business models: retail/e-commerce transactions and wholesale orders. The system ensures data consistency across these processes by linking related documents (like orders, deliveries, and invoices) and maintaining accurate records of inventory movement, customer billing, and returns.

1.2 Step-by-Step Flow

1. Quotation & Ordering: The process often begins with a `SalesQuotation` (a price offer). Once accepted, this is converted into a `SalesOrder` for wholesale customers, or a `Sale` record for retail/POS transactions.
2. Fulfillment: For wholesale orders, the system tracks the dispatch of goods via `SalesDelivery` records. These are linked to the original order to ensure that the quantity delivered does not exceed the quantity ordered.
3. Invoicing: Once goods are delivered, a `SalesInvoice` is generated. This document links back to the delivery and the original order to maintain a clear audit trail.
4. Accounts Receivable (AR): The invoice creates an `InvoiceReceivable` record, which tracks the outstanding balance.
5. Payment: When a customer makes a payment, an `ARPayment` is recorded. This payment is then linked to the specific `InvoiceReceivable` via an `ARPaymentAllocation` to mark the invoice as paid.
6. Returns & Adjustments: If goods are returned, the system uses `SaleReturn` (for retail) or `SalesOrderReturn` (for wholesale) to process the return, update inventory, and issue a `CreditNote` to adjust the customer's balance.

1.3 Key Concepts

- Denormalization: The system stores copies of certain data (like customer names or product SKUs) directly within transaction tables. This allows the system to display information quickly without needing to look up the original record every time.
- Workflow State: A status tracker (e.g., "Draft," "Confirmed," "Delivered," "Paid") that ensures documents move through the business process in the correct order.
- Polymorphic Entities: Certain records, like `Claim` or `CreditNote`, can link to multiple different types of documents (e.g., a claim could be linked to a `Sale` or a `Service`), providing flexibility in how issues are tracked.
- Trigger-Maintained Fields: Automated background rules that update totals or quantities (such as `quantity_delivered`) whenever a related document is created, preventing manual errors and ensuring data integrity.
-

AR Ageing: The process of tracking how long an invoice has been outstanding, managed through the `InvoiceReceivable` table to help the business monitor cash flow.

1.4 Business Value

- End-to-End Traceability: By linking every document from the initial quote to the final payment, the system provides a complete audit trail, making it easy to resolve customer disputes or investigate discrepancies.
- Operational Efficiency: Automated tracking of delivered and invoiced quantities prevents common errors like over-shipping or double-billing.
- Improved Cash Flow Visibility: The integrated Accounts Receivable and payment allocation features provide real-time insight into outstanding customer balances and expected revenue.
- Performance Optimization: By using denormalized data and indexed lookups, the system ensures that sales reports and search queries remain fast, even as the volume of transactions grows.

BUSINESS REQUIREMENTS DOCUMENT

User Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The User Schema feature establishes the foundation for how the Lumi ERP system manages user identities, authentication, and security. It defines the structure for storing user profiles, tracking active login sessions, monitoring login attempts for security, and maintaining an audit trail of important actions. This ensures that user data is handled consistently, securely, and in compliance with modern authentication standards.

1.2 Step-by-Step Flow

1. User Identification: When a user attempts to log in, the system retrieves their profile using their email address to verify their credentials.
2. Security Monitoring: Every login attempt is recorded, regardless of whether it succeeds or fails. This allows the system to track patterns, such as multiple failed attempts, to prevent unauthorized access.
3. Session Management: Upon a successful login, the system creates a secure session. This session is validated on every subsequent request to ensure the user is still active and their access has not expired.
4. Audit Logging: Significant security events—such as logging in, changing a password, or updating a user role—are recorded in an immutable audit log to provide a clear history of system activity.
5. User Retrieval: Authorized users can view lists of system users, filtered by criteria like name, role, or account status, to help administrators manage the user base effectively.

1.3 Key Concepts

- User Profile: The core record containing essential information like name, email, role, and account status (e.g., whether the account is active or requires a password change).
- Session: A temporary, secure link between the user and the system that tracks how long they remain logged in before needing to re-authenticate.
- Login Attempt Tracking: A security mechanism that logs sign-in activity to help the system identify and block suspicious behavior or brute-force attacks.
- Audit Log: A permanent, unchangeable record of security-sensitive actions, providing transparency and accountability for administrative and user-driven changes.
- Role-Based Access: A system that assigns specific roles (such as Admin or Staff) to users to control what they can see and do within the ERP.

1.4 Business Value

- Enhanced Security: By tracking login attempts and maintaining detailed audit logs, the system proactively protects against unauthorized access and provides a clear trail for security investigations.
-

Operational Efficiency: Administrators can easily search, filter, and manage user accounts, reducing the time spent on routine user administration tasks.

- Reliable Access Control: The robust session management ensures that users are only granted access when their credentials are valid and their accounts are active, maintaining the integrity of the ERP system.
- Compliance Readiness: The built-in audit trail supports organizational requirements for tracking sensitive changes, which is critical for internal oversight and regulatory compliance.

BUSINESS REQUIREMENTS DOCUMENT

Login Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Login Page is the secure entry point for the Lumi ERP system. It is designed to provide a clean, user-friendly interface that verifies user credentials and ensures that only authorized personnel can access the product management dashboard. The page includes proactive validation to help users identify account issues quickly and automatically redirects logged-in users to their workspace to save time.

1.2 Step-by-Step Flow

1. Automatic Session Check: When the page loads, the system automatically checks if the user is already signed in. If a valid session is detected, the user is immediately taken to the Product List page.
2. User Identification: The user enters their email address. As they type, the system checks in real-time if the email exists in our records. If the email is not found, an error message appears to alert the user.
3. Credential Entry: The user enters their password in a masked field to ensure privacy.
4. Authentication: Upon clicking the "Login" button, the system verifies the provided email and password.
5. Access Granted: If the credentials are correct, the system grants access and redirects the user to the Product List page.

1.3 Key Concepts

- Session Persistence: The ability of the system to remember a user, allowing them to bypass the login screen if they have already authenticated recently.
- Real-time Validation: A feature that checks the validity of the email address while the user is still typing, providing immediate feedback rather than waiting until the form is submitted.
- Masked Input: A security standard for password fields where characters are hidden (usually as dots or asterisks) to prevent others from seeing the password as it is typed.
- Redirect: An automated action that moves the user to a different page (the Product List) once a specific condition, such as a successful login, is met.

1.4 Business Value

- Improved User Experience: By automatically redirecting active users and providing real-time feedback on email entry, we reduce friction and help users get to their work faster.
- Enhanced Security: Masked password fields and server-side authentication ensure that sensitive account information remains protected.
-

Operational Efficiency: The clear, focused interface minimizes login errors, reducing the number of support inquiries related to account access and authentication.

2. Logic

2.1 Overview

The Login Page feature provides a secure entry point for users to access the Lumi ERP system. It is designed to be intuitive, ensuring that users are only prompted to log in when necessary, while providing immediate feedback if their account information is incorrect. The system also includes a proactive check to see if a user is already logged in, automatically directing them to their workspace if they have an active session.

2.2 Step-by-Step Flow

1. Automatic Session Check: When the login page loads, the system automatically checks if you are already logged in. If you have an active session, you are immediately taken to the Product List page.
2. Email Verification: As you enter your email address, the system checks in the background to confirm that the email exists in our records. If the format is incorrect or the email is not found, you will be notified.
3. Login Attempt: Once you enter your password and click the "Login" button, the system verifies your credentials.
4. Authentication & Access: If the email and password match our records, the system securely saves your session and redirects you to the Product List page.
5. Error Handling: If the credentials do not match or are missing, the system will display an error message, preventing unauthorized access.

2.3 Key Concepts

- Session Token: A secure digital "key" provided to your browser after a successful login, which allows you to stay logged in without re-entering your password for a set period.
- Credential Verification: The process of comparing your entered password against the securely stored version in our system to ensure your identity is confirmed without ever exposing your actual password.
- Client-Side Validation: Immediate checks performed by the login page to ensure that required fields (like email and password) are filled out correctly before the information is even sent to our servers.

2.4 Business Value

- Improved User Experience: By automatically detecting active sessions, returning users can jump straight into their work without unnecessary login steps.
-

Enhanced Security: By using secure hashing for passwords and validating credentials on the server side, we ensure that user data remains protected against unauthorized access.

- Reduced Friction: Real-time email validation helps users identify typos or registration issues immediately, preventing frustration during the login process.

3. Data

3.1 Overview

The login feature for the Lumi ERP system provides a secure way for users to access their accounts and maintain their logged-in status. It handles the initial verification of credentials and manages ongoing access sessions to ensure that only authorized users can view the product list.

3.2 Step-by-Step Flow

1. User Login: The user enters their email and password. The system verifies these credentials against our records.
2. Session Creation: If the credentials are correct, the system generates a secure digital "key" (session token) that identifies the user for the next 24 hours.
3. Access Grant: This key is stored in the user's browser, allowing them to navigate to the Product List page.
4. Automatic Verification: Whenever the user refreshes the page or returns to the site, the system automatically checks for this valid key to confirm the user is still logged in.
5. Session Expiration: If the key is missing or has expired (after 24 hours), the system will require the user to log in again to ensure account security.

3.3 Key Concepts

- Authentication: The process of confirming that the email and password provided match an existing user account in our system.
- Session: A temporary, secure connection that keeps a user logged in so they don't have to re-enter their password every time they click a new page.
- Session Token: A unique, encrypted identifier used by the system to recognize a specific user's active session.
- Expiration: A security measure that automatically ends a session after 24 hours, requiring the user to re-authenticate to maintain access.

3.4 Business Value

-

Security: By validating credentials and using time-limited session tokens, we protect sensitive business data from unauthorized access.

- User Experience: The system remembers the user, allowing for a seamless transition between pages without the frustration of repeated logins.
- Reliability: The automated check on page load ensures that users are always directed to the correct area of the application based on their current login status.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/auth/logout

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The logout feature ensures that when a user chooses to sign out of the Lumi ERP system, their active session is securely terminated. This process invalidates the user's current access credentials in our database and removes the digital "key" (cookie) stored on their browser, preventing any further unauthorized access using that specific session.

1.2 Step-by-Step Flow

1. Identify Session: The system looks for the user's unique session token stored in their browser cookies.
2. Verify Existence: The system checks if a session token was provided. If no token is found, the request is rejected.
3. Validate Status: The system searches the database to confirm the session is legitimate and has not already been closed. If the session is missing or already revoked, the request is rejected.
4. Revoke Access: The system updates the database to mark the session as officially closed, effectively disabling it.
5. Clear Browser Data: The system sends a command to the user's browser to delete the session cookie.
6. Confirm Logout: The system sends a success message to the user, confirming they have been logged out.

1.3 Key Concepts

- Session Token: A unique digital identifier that acts as a temporary "key" to keep a user logged in while they navigate the application.
- Revocation: The act of officially canceling a session in the database so that it can no longer be used to access the system.
- Cookie: A small piece of data stored by the browser that holds the session token, allowing the system to recognize the user across different pages.

1.4 Business Value

This feature is critical for maintaining the security and integrity of the Lumi ERP system. By explicitly revoking sessions, we ensure that once a user logs out, their account cannot be accessed by anyone else using the same device or browser. This protects sensitive business data and ensures that user activity is accurately tracked and controlled.

2. Data

2.1 Overview

The logout feature ensures that when a user chooses to sign out of the Lumi ERP system, their current session is securely terminated. This process verifies the user's active connection and updates our records to ensure that the session can no longer be used to access the system, effectively protecting the user's account from unauthorized access after they have left.

2.2 Step-by-Step Flow

1. Session Verification: The system checks the database to confirm that the user’s current session is valid, active, and has not yet expired.
2. Validation Check: If the system cannot find an active session (for example, if the user is already logged out or the session has timed out), it informs the user that the request is unauthorized.
3. Session Revocation: If a valid session is found, the system updates the database to mark that specific session as "revoked" using the current timestamp.
4. Confirmation: Once the database has been successfully updated, the system sends a confirmation back to the user to signal that the logout process is complete.

2.3 Key Concepts

- Session: A temporary digital "handshake" that keeps a user logged in while they navigate the application.
- Revocation: The act of officially canceling a session, ensuring that the digital key used to access the system is no longer valid.
- Unauthorized Status: A standard response indicating that the system could not identify a valid, active session to log out.

2.4 Business Value

This feature is critical for maintaining the security and integrity of the Lumi ERP platform. By explicitly revoking sessions, we prevent "session hijacking," where an unauthorized party might attempt to use an old, active session to gain access to sensitive business data. This provides users with peace of mind, knowing that their account is fully secured the moment they click "logout."

BUSINESS REQUIREMENTS DOCUMENT

GET /api/auth/me

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get Current User" feature allows the application to identify who is currently logged in. When a user opens the application, the system automatically checks their session to retrieve their profile details. This ensures the interface can display the correct user information and immediately identify if the user needs to take action, such as updating their password, before they begin their work.

1.2 Step-by-Step Flow

1. Session Verification: The system receives a request from the application containing the user's secure session token.
2. Identity Confirmation: The system validates the token to confirm the user is who they claim to be. If the token is invalid or missing, the system denies access.
3. Profile Retrieval: Once the identity is confirmed, the system looks up the user's specific account details in the database.
4. Data Delivery: The system sends back the user's profile information, including their name, email, account status, and a specific flag indicating if they are required to change their password.

1.3 Key Concepts

- Session Token: A secure digital "key" provided by the system that proves a user has already successfully logged in.
- Account Status: Information regarding whether an account is currently active or if the user is required to perform a security action, such as a password reset.
- Unauthorized Access: A security response triggered when the system cannot verify a user's identity, preventing them from accessing private account data.

1.4 Business Value

- Seamless User Experience: By automatically identifying the user upon login, the application can personalize the experience immediately without requiring the user to re-enter their details.
- Proactive Security: By including a "must change password" flag, the system can automatically redirect users to a password reset screen if their account security requires it, ensuring compliance with company security policies without manual intervention.
- Reliable Session Management: This feature provides a consistent way for the application to verify that a user's session is still valid, protecting sensitive data from unauthorized access.

2. Data

2.1 Overview

The "Get Current User" feature allows the system to identify who is currently logged in. When a user visits the application, this feature retrieves their profile information so the interface can display the correct user details and determine if any immediate actions—such as a mandatory password update—are required.

2.2 Step-by-Step Flow

1. Session Verification: The system checks the user's active session token to confirm their identity. If the token is missing or expired, the request is rejected.
2. User Retrieval: Once the identity is confirmed, the system looks up the user's profile in the database using their unique ID. If the user account is not found, the request is rejected.
3. Data Sanitization: The system filters the user's profile information to ensure only non-sensitive, relevant details are shared.
4. Response: The system returns the user's profile data, including their name, email, and status flags, to the application.

2.3 Key Concepts

- Session Token: A digital "key" that proves a user has successfully logged in and is currently authorized to access the system.
- Sanitization: The process of removing sensitive internal data (like security credentials) before sending information to the user's browser, ensuring only safe, public-facing details are shared.
- Status Flags: Indicators within the user profile—such as whether a password change is required or if the account is currently active—that help the application decide how to guide the user.

2.4 Business Value

This feature is essential for providing a personalized and secure user experience. By allowing the application to "know" who is logged in, the system can automatically tailor the interface to the individual. Furthermore, by including status flags like "must change password," the system can proactively prompt users to perform necessary security updates, ensuring compliance and account safety without blocking the user from accessing the initial login state.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/users/validate

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Logic

1.1 Overview

The "Validate User" feature provides a secure way for the system to check if a specific email address is already registered in our database. This tool is designed to help verify user status quickly while ensuring that only authorized personnel can perform these checks.

1.2 Step-by-Step Flow

1. Security Check: The system first verifies that the person making the request is logged in and has the necessary permissions to perform user validation.
2. Data Format Check: The system ensures the information provided (email, name, and role) follows the required format. If the data is formatted incorrectly, the request is rejected.
3. Database Search: The system cleans the provided email address (removing extra spaces and converting it to lowercase) and searches the database to see if a matching record exists.
4. Result Delivery: The system returns a clear confirmation stating whether the user exists in the database or not, along with the email address that was checked.

1.3 Key Concepts

- Authentication: The process of confirming the identity of the person or system making the request to ensure they are who they claim to be.
- Authorization: The process of checking if the authenticated user has the specific "permission" required to access this validation tool.
- Payload Validation: A quality-control step that ensures the information sent to the system is complete and correctly formatted before the system attempts to process it.
- Normalization: A standardizing process where the system cleans up input (like removing accidental spaces or changing capital letters to lowercase) to ensure the database search is accurate.

1.4 Business Value

This feature improves data integrity and user experience by allowing the system to proactively identify existing accounts. By automating this check, we prevent duplicate registrations and provide immediate feedback during user management tasks, ensuring that our records remain clean and accurate without requiring manual database searches.

2. Data

2.1 Overview

The User Validation feature provides a way to check if an email address is valid and available for use before attempting to create a new user account. This helps prevent errors during the registration process by giving immediate feedback on whether an email address is correctly formatted or if it is already registered in the system.

2.2 Step-by-Step Flow

1. Request Submission: The system receives a request containing an email address to be checked.
2. Format Verification: The system first checks if the provided email follows a standard, valid format (e.g., containing an "@" symbol and a domain).
3. Database Lookup: If the format is correct, the system searches the database to see if that specific email address is already associated with an existing user account.
4. Result Generation: The system returns a response indicating whether the email is valid and available. If there is an issue (such as an incorrect format or the email is already taken), the system provides a clear error message.

2.3 Key Concepts

- Format Validation: A preliminary check to ensure the input looks like a real email address before performing more intensive database operations.
- Uniqueness Check: A verification step that ensures no two users in the system share the same email address.
- Normalization: The process of cleaning up the input (removing extra spaces and converting to lowercase) to ensure the database search is accurate and consistent.
- Validation Status: A simple "true/false" indicator that tells the user if they can proceed with the current information.

2.4 Business Value

This feature improves the user experience by reducing friction during account creation. By catching issues like duplicate emails or typos early, the system prevents failed registration attempts and ensures that user data remains clean and unique within the database. It provides a proactive way to guide users toward successful account setup.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/auth/login

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The login feature provides a secure way for users to access the Lumi ERP system. It verifies user credentials and establishes a temporary session. To protect the system and user data, the feature includes built-in safeguards against unauthorized access, automated attacks, and malicious attempts to guess user information.

1.2 Step-by-Step Flow

1. Security Screening: The system first checks if the request is coming from a trusted source. If the request originates from an unauthorized external location, it is blocked immediately.
2. Traffic Control: The system checks if there have been too many login attempts from the user's current location. If the limit is exceeded, the request is paused to prevent automated brute-force attacks.
3. Data Validation: The system ensures the login information provided is formatted correctly (e.g., a valid email structure). If the information is incomplete or malformed, the request is rejected.
4. Credential Verification: The system checks the provided email and password against our secure records. It also confirms that the account is active and not locked.
5. Session Creation: If the credentials are correct, the system creates a secure session that remains valid for 24 hours.
6. Response: Upon success, the system provides a session ID and an expiration timestamp. If any part of the authentication fails, the system returns a generic error message to protect account privacy.

1.3 Key Concepts

- CSRF (Cross-Site Request Forgery) Protection: A security measure that ensures login requests are only accepted from our own application, preventing malicious websites from performing actions on behalf of a user.
- Rate Limiting: A defensive mechanism that limits the number of login attempts allowed from a single location within a specific timeframe to stop automated "guessing" attacks.
- User Enumeration Prevention: A security practice where the system provides the same generic error message regardless of whether the email was wrong or the password was incorrect. This prevents attackers from discovering which email addresses are registered in our system.
- Constant-Time Verification: A technique used during password checking to ensure that the time taken to process a login attempt does not reveal information about whether the password was partially correct.

1.4 Business Value

This feature balances user convenience with high-level security. By implementing robust protections like rate limiting and generic error messaging, we significantly reduce the risk of account takeovers and data breaches. This ensures that the Lumi ERP remains a trusted environment for our users while maintaining compliance with modern security standards.

2. Data

2.1 Overview

The login feature provides a secure way for users to access the Lumi ERP system. It validates user credentials and establishes a temporary session upon a successful match. The system is designed with high security standards to protect against common cyber threats, ensuring that login attempts remain private and resistant to unauthorized access.

2.2 Step-by-Step Flow

1. Request Submission: The user submits their email and password to the login endpoint.
2. Input Normalization: The system automatically cleans the email address (removing extra spaces and converting it to lowercase) to ensure consistency.
3. Credential Verification: The system checks the provided credentials against the database.
4. Security Validation: The system verifies the password and checks if the account is active and not locked.
5. Session Creation: If all checks pass, the system generates a unique session ID that remains valid for 24 hours.
6. Response: The system returns the user's details and the new session ID. If any part of the process fails (e.g., wrong password, inactive account, or unknown email), the system returns a generic error message to prevent attackers from guessing valid account information.

2.3 Key Concepts

- Generic Error Handling: Regardless of why a login fails, the system provides the same "Invalid email or password" message. This prevents malicious actors from determining if an email address exists in our system.
- Constant-Time Verification: A security technique that ensures the system takes the same amount of time to process a login attempt, whether the password is correct or incorrect, preventing timing-based attacks.
- CSRF Protection: A security measure that ensures login requests are coming from our legitimate application, preventing unauthorized third-party sites from hijacking user sessions.
- Session Expiry: For security, every login creates a session that automatically expires after 24 hours, requiring the user to re-authenticate.

2.4 Business Value

- Enhanced Security: By using generic error messages and constant-time verification, we significantly reduce the risk of "user enumeration" attacks, where hackers try to identify valid user accounts.
- Data Integrity: Normalizing email inputs ensures that users can log in regardless of how they type their email (e.g., capitalization), reducing support tickets related to login issues.
- Compliance and Safety: The inclusion of CSRF checks and account status verification (checking for locked or inactive accounts) ensures that only authorized, active users can access the ERP, protecting sensitive business data.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/users

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides administrators with a secure way to view a list of all users registered in the Lumi ERP system. To ensure the most relevant information is prioritized, the list is automatically sorted to display the newest users at the top. Access to this information is strictly limited to authorized administrators to maintain data security.

1.2 Step-by-Step Flow

1. Identity Verification: The system checks if the person requesting the list is logged in. If they are not, the request is denied.
2. Permission Check: The system verifies that the logged-in user holds an "admin" role. If the user does not have administrative privileges, the request is blocked.
3. Data Retrieval: Once authorized, the system fetches the user directory from the database, automatically organizing the records so that the most recently created accounts appear first.
4. Display: The system presents the requested user information, including their unique ID, email address, role, account creation date, and full name.

1.3 Key Concepts

- Authentication: The process of confirming the identity of the user to ensure they are logged into the system.
- Authorization: The process of verifying that the logged-in user has the specific "admin" permissions required to view sensitive user data.
- Descending Order: A sorting method used here to ensure that the "newest" users are always listed at the top of the results.
- User Directory: The collection of account details (such as names and roles) that administrators need to manage the system effectively.

1.4 Business Value

This feature empowers administrators to efficiently monitor system growth and manage user accounts. By prioritizing the newest users, administrators can quickly identify and verify recent sign-ups or troubleshoot onboarding issues without having to manually search through the entire database. Furthermore, by enforcing strict role-based access, the feature ensures that sensitive user information remains protected and accessible only to those responsible for system administration.

2. Data

2.1 Overview

This feature provides administrators with a secure way to view a list of all users registered in the Lumi ERP system. To ensure the list is easy to manage, the results are automatically sorted so that the most recently created accounts appear first. The system also includes built-in safeguards to ensure that only authorized administrators can access this sensitive information.

2.2 Step-by-Step Flow

1. Authorization Check: When a request is made, the system first verifies that the person making the request holds an "admin" role. If they do not, the request is blocked.
2. Parameter Setup: The system checks for specific display preferences (such as how many users to show at once). If no preferences are provided, it defaults to showing 20 users starting from the most recent.
3. Data Retrieval: The system queries the database to pull the user information, ensuring the list is ordered by the creation date in descending order (newest first).
4. Response Delivery: The system returns the requested list of users along with a summary of the display settings used (the limit and offset) to confirm the data provided.

2.3 Key Concepts

- Admin Authorization: A security gate that restricts access to the user list, ensuring only verified administrators can view the data.
- Pagination: A method of breaking a large list of users into smaller, manageable chunks, controlled by "limit" (how many to show) and "offset" (where to start in the list).
- Chronological Sorting: The automatic organization of data based on the time of creation, ensuring the newest users are always at the top of the list.

2.4 Business Value

This feature empowers administrators to efficiently oversee the user base within the Lumi ERP. By providing a sorted, paginated view, administrators can quickly identify new account registrations and manage user access without having to manually search through the entire database. The strict authorization layer ensures that sensitive user information remains protected and compliant with internal security policies.

BUSINESS REQUIREMENTS DOCUMENT

Company List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Company List Page is a central hub within the Lumi ERP system that allows users to view and manage all registered companies. This page provides a clear, organized table view of company information, ensuring that users can easily identify and access specific company records for updates.

1.2 Step-by-Step Flow

1. Page Initialization: When the user navigates to the Company List page, the system automatically triggers a request to retrieve the full list of companies.
2. Loading State: While the data is being fetched, the user sees a loading indicator to confirm the system is working.
3. Data Display: Once the data is retrieved, the system populates a table with the following details for each company: Name, Address, Country, and Currency.
4. Error Handling: If the system fails to retrieve the data, an error message is displayed to inform the user.
5. Navigation: Each row in the table includes an "Edit" button. Clicking this button redirects the user to a dedicated page where they can modify the details of that specific company.

1.3 Key Concepts

- Company Table: A structured list view that displays key business information for each company in a clean, readable format.
- Loading State: A visual cue that informs the user that the system is currently processing a request, preventing confusion during brief wait times.
- Edit Action: A functional link associated with each company row that allows for quick navigation to the editing interface for that specific record.
- Setup Menu: The navigation context that helps users understand they are currently working within the "Setup" area of the ERP system.

1.4 Business Value

This feature streamlines administrative tasks by providing a centralized, easy-to-navigate view of all company entities. By enabling quick access to company details and providing a direct path to the editing interface, the page reduces the time and effort required for users to maintain accurate company records, ultimately improving data management efficiency within the Lumi ERP.

2. Logic

2.1 Overview

The Company List Page feature provides a centralized view for users to browse all companies registered within the Lumi ERP system. This page acts as a directory, allowing you to see key details for every company at a glance, ensuring that all organizational data is easily accessible and organized in one place.

2.2 Step-by-Step Flow

1. The system receives a request to display the list of companies.
2. The system retrieves the complete collection of company records from the database.
3. The system organizes this data into a clear, readable format, ensuring each company includes its name, address, country, and currency.
4. The system presents this compiled list to the user on the Company List Page.
5. If the system encounters an issue while gathering this information, it will notify the user that the list could not be retrieved.

2.3 Key Concepts

- Company Record: The core set of information stored for each business entity, including its name, location, and financial currency.
- Row Identifier: A unique internal reference for each company that allows the system to link specific entries to actions, such as clicking an "Edit" button to update details.
- Data Mapping: The process of taking raw information from the system's database and presenting it in a structured, user-friendly layout on your screen.

2.4 Business Value

This feature improves operational efficiency by providing a single source of truth for all company entities. By having a clear, browsable list, users can quickly verify company information, maintain accurate records, and easily navigate to specific company profiles for further management or updates.

3. Data

3.1 Overview

The Company List Page is a centralized dashboard within the Lumi ERP system that allows you to view all registered companies in one place. This feature acts as a directory, pulling data from our secure database and presenting it in a clean, organized table format so you can easily manage and review your organization's entities.

3.2 Step-by-Step Flow

1. The system initiates a request to the Lumi ERP backend to retrieve the complete list of registered companies.
2. The system receives the raw data, which includes details such as the company name, physical address, country of operation, and local currency.
3. The system automatically standardizes this information to ensure it matches our internal display format.
4. The processed data is then populated into the Company List table, where each company is assigned a unique identifier to allow for future actions, such as editing specific records.

3.3 Key Concepts

- Company Entity: A single record representing a business entity within the ERP, containing its core details like name, location, and financial settings.
- Data Standardization: A background process that ensures information from our database is presented consistently in the user interface, regardless of how it is stored technically.
- Unique Identifier: A hidden, permanent reference number assigned to each company that ensures the system always knows exactly which record you are viewing or editing.

3.4 Business Value

This feature provides a "single source of truth" for your company data. By offering a clear, browsable list, it eliminates the need to search through disparate records, reduces manual data entry errors, and provides a reliable foundation for managing company-specific settings across the entire ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

Company Edit

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Company Edit page allows administrators to update essential business information and configure operational settings for their company within the Lumi ERP system. The page is organized into two main sections—Details and Settings—ensuring that all company-specific data, from contact information to inventory and point-of-sale (POS) preferences, can be managed in one centralized location.

1.2 Step-by-Step Flow

1. Loading the Page: When you navigate to the Company Edit page, the system automatically retrieves the current company's existing data and populates all fields. The "Details" tab is displayed by default.
2. Updating Details: You can modify core information such as the company name, address, contact details (phone, email, fax), and tax identification numbers.
3. Configuring Settings: By switching to the "Settings" tab, you can manage advanced operational preferences, including:

* Product Management: Defining custom product labels, monitoring specific product types, and setting barcode standards.
* POS & Sales: Configuring default customer settings, payment overage rules, and receipt printing preferences.
* Stock & Purchasing: Toggling permissions for editing quantities in stock orders, returns, and transfers, as well as visibility settings for purchasing and serial numbers.
* Reporting: Setting the character used to separate columns in exported CSV files.

4. Saving Changes: Once you have finished your updates, clicking the "Save" button submits all changes from both sections to the system. Upon a successful save, you will be redirected back to the main Company List page.
5. Canceling: If you wish to discard your changes, clicking the "Cancel" button will clear the form and return you to the Company List page without saving.

1.3 Key Concepts

– Details Section: The primary area for managing static company identity, such as contact info, business name, and regional settings (time zone/country).
– Settings Section: A comprehensive area for operational configuration, covering inventory, sales, and reporting preferences.
–

Form Persistence: The system ensures that data entered or modified in one tab remains intact while you navigate to the other, allowing for a seamless editing experience before final submission.

– Tooltips: Informational icons provided throughout the page to explain specific fields, such as internal company codes, business brand names, and custom product attributes.

1.4 Business Value

This feature provides the flexibility required to keep company records accurate and operational workflows optimized. By centralizing both administrative details and granular system settings, users can quickly adapt the ERP to changing business needs—such as updating contact information, adjusting stock management rules, or refining POS behavior—without needing technical support. This ensures the system remains aligned with the company's current operational processes.

2. Logic

2.1 Overview

The Company Edit feature provides a centralized interface for administrators to update essential company information and operational settings within the Lumi ERP system. This page ensures that business details, product configurations, and point-of-sale (POS) preferences are accurately maintained and synchronized across the platform.

2.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves the current company’s existing data and populates the form fields.
2. Data Review & Modification: The user reviews and updates information across two main areas:

* Details Section: Includes core business information such as name, address, contact details, and regional settings (time zone, currency).

* Settings Section: Includes advanced configurations for product labeling, custom attributes, barcode types, POS behavior, stock management, and purchasing workflows.

3. Validation: Before saving, the system ensures that all mandatory fields (such as company name, code, address, and tax settings) are correctly filled.
4. Submission: Upon clicking the save button, the system bundles all updated information and sends it to the server.
5. Confirmation & Navigation: If the update is successful, the system automatically redirects the user back to the main Company List page.

2.3 Key Concepts

- Company Details: The foundational business information required for system identification and reporting.
- Product Attributes: Customizable labels and settings that allow the business to define how products are categorized and displayed, including mobile-specific visibility toggles.
- POS Settings: Operational controls for the point-of-sale interface, such as payment overage limits and receipt printing preferences.
- Operational Toggles: Various switches that control specific business logic, such as whether users can edit received quantities in stock orders or view specific purchasing states.
- Data Mapping: The process by which the system ensures that the information stored in the database is correctly displayed in the corresponding form fields for the user to edit.

2.4 Business Value

This feature empowers users to maintain accurate company records and fine-tune operational settings without needing technical intervention. By providing a comprehensive and structured edit page, the business can ensure that its ERP configuration remains aligned with current workflows, tax requirements, and inventory management practices, ultimately leading to more reliable reporting and smoother daily operations.

3. Data

3.1 Overview

The Company Edit feature allows administrators to manage and update core business information and operational settings for their organization within the Lumi ERP system. This page provides a centralized interface to configure everything from basic contact details to specific inventory, purchasing, and point-of-sale (POS) preferences.

3.2 Step-by-Step Flow

1. Loading Data: When you open the Company Edit page, the system automatically retrieves the current company's existing information and populates the form fields.
2. Review and Edit: You can review and modify details across several categories, including:

* Company Details: Basic information like name, address, contact details, and regional settings (time zone, currency).

* Product Configuration: Custom labels, product type monitoring, and mobile visibility settings for product attributes.

* Operational Settings: Barcode types, POS preferences (such as receipt printing and overpayment limits), and stock/purchasing workflow toggles.

* Reporting: Configuration for CSV file formatting.

3. Validation: Once you submit your changes, the system performs a check to ensure all mandatory fields (such as Name, Code, Address, and Time Zone) are filled out correctly.
4. Saving and Navigation: If the information is valid, the system saves your updates and automatically redirects you back to the main Company List page.

3.3 Key Concepts

- Company Profile: The foundational set of data that defines your business identity and regional operational standards within the ERP.
- Operational Toggles: Simple "on/off" switches that allow you to customize how the system handles specific workflows, such as editing received quantities in stock orders or showing specific states in purchasing.
- Custom Attributes: Flexible fields that allow you to define and label product information in a way that best fits your specific business needs.
- Validation: A built-in safety mechanism that prevents the form from being saved if essential information is missing, ensuring data consistency.

3.4 Business Value

This feature provides the flexibility needed to keep your ERP configuration aligned with your evolving business requirements. By allowing users to easily update operational settings—such as stock management rules or POS behaviors—without needing technical support, the company can maintain accurate records and ensure that internal processes remain efficient and consistent across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Finance - Payment Types List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Payment Types List feature provides a centralized dashboard for managing how different payment methods are configured within the Lumi ERP system. Users can view, search, and filter through all active or inactive payment types, such as cash, credit cards, or debit cards. The interface is designed to help finance teams quickly verify payment provider details, fee rates, and specific processing rules (like refund capabilities or invoice receivable settings) in a clear, tabular format.

1.2 Step-by-Step Flow

1. Initial Load: When the page opens, the system automatically displays a list of all "Active" payment types, showing 20 items per page.
2. Navigation: Users can toggle between "Active" and "Inactive" tabs to switch the view of payment types.
3. Filtering: Users can narrow down the list by entering a name or selecting specific criteria from dropdown menus (Type, Refund status, or Invoice Receivable status).
4. Search: Clicking the "Search" button applies the selected filters, resets the view to the first page, and updates the table with the relevant results.
5. Reviewing Details: The table displays key information for each payment type, including the provider, fee rates, and operational settings.
6. Taking Action:

* Clicking a payment provider name navigates the user to the relevant Customer Details page.

* Clicking the "Show" button in the Stores column opens the mapping list for that payment type.

* Clicking the "Edit" button allows the user to modify the configuration of a specific payment type.

1.3 Key Concepts

- Payment Type: A specific method of payment (e.g., Cash, Credit Card) configured in the system.
- Active/Inactive Status: A toggle that filters the list to show only currently used payment methods or those that have been archived/deactivated.
- Pagination: A system that breaks the list into smaller, manageable pages (20 items per page) to ensure the interface remains fast and easy to read.
- Filter Bar: A set of controls that allows users to refine the list based on specific attributes like name, type, or processing rules.
- Mapping: A feature that links a payment type to specific store locations or business rules.

1.4 Business Value

This feature streamlines financial administration by providing a single source of truth for payment configurations. By allowing users to easily search and filter payment types, the system reduces the time spent looking up provider details or fee structures. Furthermore, the ability to quickly navigate to customer details or mapping configurations ensures that finance teams can maintain accurate records and respond to payment-related inquiries with minimal effort.

2. Logic

2.1 Overview

The Payment Types List feature provides a centralized view for managing how payments are processed within the Lumi ERP system. Users can browse, search, and filter through all configured payment types—such as credit cards or cash—to quickly locate specific payment methods and view their associated settings, such as provider fees and refund capabilities.

2.2 Step-by-Step Flow

1. Initial Load: When the page first opens, the system automatically displays a list of all "Active" payment types, showing 20 items per page.
2. Applying Filters: Users can refine the list using the filter bar. Available filters include the payment name, type, refund status, invoice receivable settings, and an active/inactive status toggle.
3. Search Execution: Upon clicking the "Search" button, the system clears the current view, resets to the first page of results, and fetches the updated list based on the selected criteria.
4. Data Display: The system retrieves the relevant payment data and organizes it into a table. This includes details like the payment provider, fee rates, and specific operational flags (e.g., whether refunds are enabled).
5. Pagination: If the results exceed the page size, the system provides navigation controls to move between pages, ensuring the interface remains clean and easy to navigate.

2.3 Key Concepts

- Payment Type: A specific method of payment (e.g., Cash, Credit Card, Debit Card) configured within the system.
- Filters: Search criteria that allow users to narrow down the list by specific attributes, such as whether a payment type is currently active or if it allows refunds.
- Pagination: A method of breaking the list into smaller, manageable chunks (pages) to improve performance and readability.

- Provider Details: Information regarding the external service or bank handling the transaction, including any associated fee rates.
- Operational Flags: Settings that dictate how the system handles specific payment types, such as whether to skip invoice receivables or allow refunds.

2.4 Business Value

This feature improves operational efficiency by allowing finance teams to quickly audit and manage payment configurations. By providing robust search and filtering capabilities, users can easily verify provider fee rates and payment settings, ensuring that financial data remains accurate and that payment processing rules are correctly applied across the organization.

3. Data

3.1 Overview

The Payment Types List feature provides a centralized view for managing how your business processes incoming payments. It allows finance team members to browse all configured payment methods—such as credit cards or digital payment services—in a clear, organized table. The feature includes search capabilities to quickly locate specific methods and pagination to keep the interface clean and easy to navigate when managing a large number of payment options.

3.2 Step-by-Step Flow

1. Requesting Data: When you open the Payment Types screen, the system retrieves the full list of available payment methods from the database.
2. Applying Filters: If you enter a name into the search bar, the system narrows down the list to show only the payment types that match your search term.
3. Organizing Results: The system divides the list into manageable pages based on your preferred number of rows per page.
4. Calculating Totals: The system calculates the total number of pages and items available, ensuring the navigation controls (like "Next" or "Previous" buttons) are accurate.
5. Displaying Information: The system formats the raw data into a user-friendly list, showing key details like the provider name, associated fees, and specific settings (such as whether refunds are enabled or if invoice receivables should be skipped).

3.3 Key Concepts

- Payment Type: A specific method used to receive funds, such as a credit card, bank transfer, or digital wallet.

- Search Filter: A tool that allows you to find a specific payment method by typing part of its name.
- Pagination: A navigation feature that breaks a long list of items into smaller, separate pages to improve performance and readability.
- Provider Fee Rate: The percentage or cost charged by the payment service provider for processing a transaction.
- Refund Capability: A setting that indicates whether a specific payment method supports the processing of customer refunds.

3.4 Business Value

This feature streamlines financial operations by providing a single source of truth for all payment methods. By allowing users to quickly search and filter through these options, the finance team can reduce administrative time spent looking up payment configurations. Furthermore, the clear display of provider fees and processing rules ensures that staff can easily verify payment settings, leading to more accurate financial reporting and better control over payment processing workflows.

BUSINESS REQUIREMENTS DOCUMENT

Areas - District

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Areas - District" feature provides a centralized dashboard for users to view, search, and manage district information within the Lumi ERP system. This page allows users to quickly locate specific districts by filtering through names, provinces, or regencies, and provides a clear, paginated list of all available district records.

1.2 Step-by-Step Flow

1. Accessing the Page: Users navigate to the "Areas - District" page via the main "Setup" menu and the "Areas" sub-menu.
2. Filtering Data: Users can narrow down the list of districts by entering a name or selecting a specific Province or Regency/Municipality from the filter bar.
3. Executing Search: Upon clicking the "Search" button, the system refreshes the list to display only the records that match the selected criteria.
4. Viewing Results: The system displays a table containing the District Code (read-only), District Name, associated Regency/Municipality, and Province.
5. Navigation: Users can click on a row to view more details about a specific district, or use the navigation tabs to switch between related area categories (Province, Regency, or Village).
6. Pagination: If the list is long, users can move between pages using the pagination controls at the bottom of the screen, which automatically updates the data view.

1.3 Key Concepts

- Filter Bar: A set of input fields and dropdowns that allow users to refine the data displayed in the table based on specific criteria.
- Data Table: The primary display area that lists district records, showing key information like codes and geographic hierarchy.
- Pagination: A navigation tool that breaks large lists of data into smaller, manageable pages to improve performance and readability.
- Navigation Tabs: A quick-access menu that allows users to jump between different geographic levels (Province, Regency, District, Village) without returning to the main menu.
- Read-Only Field: A data point (such as the District Code) that is visible to the user but cannot be modified directly on this screen.

1.4 Business Value

This feature streamlines administrative tasks by providing a fast, intuitive way to manage geographic data. By enabling precise filtering and easy navigation between related area types, it reduces the time spent searching for records and ensures that users can efficiently maintain accurate district information within the ERP system.

BUSINESS REQUIREMENTS DOCUMENT

Finance - Payment Type Mapping List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Payment Type Mapping feature provides a centralized dashboard within the Lumi ERP system to manage how different payment methods (such as Cash, Credit, or QRIS) are assigned to specific store locations. This tool allows finance administrators to view, filter, and maintain the status of these payment configurations to ensure accurate financial reporting and operational consistency across all store branches.

1.2 Step-by-Step Flow

1. Initial Loading: When you open the page, the system automatically retrieves the full list of existing payment mappings, along with the complete lists of available stores and payment types to populate your filter options.
2. Filtering: You can narrow down the list of mappings by selecting a specific store, a particular payment method, or by filtering for only "Active" or "Inactive" configurations.
3. Applying Filters: Once you have selected your criteria, clicking the "Show" button updates the table to display only the records that match your search.
4. Reviewing Data: The table displays the results in a clear list, showing the store name, the associated payment type, and a visual indicator (a green checkmark) if the mapping is currently active.
5. Editing: Each row includes an "Edit" button, allowing you to quickly access and modify the details of a specific payment mapping.

1.3 Key Concepts

- Payment Type Mapping: The association between a specific store and a payment method, defining which payment options are valid for that location.
- Filter Bar: A set of dropdown menus that allow you to search for specific mappings based on store, payment type, or status without having to scroll through the entire list.
- Active Status: A toggle-like indicator that shows whether a payment method is currently enabled for use at a specific store.
- Pagination: A feature that organizes large lists of data into manageable pages, ensuring the interface remains clean and easy to navigate.

1.4 Business Value

This feature streamlines financial setup by providing a single source of truth for payment configurations. By allowing users to easily filter and verify which payment methods are active at which stores, the system reduces the risk

of configuration errors, simplifies the onboarding of new payment methods, and ensures that store-level financial data remains accurate and consistent across the organization.

2. Logic

2.1 Overview

The Payment Type Mapping feature allows users to manage and view how specific payment methods are assigned to different store locations within the Lumi ERP system. This feature provides a centralized interface to see which payment types are active for each store, ensuring that financial transactions are correctly categorized and controlled across the organization.

2.2 Step-by-Step Flow

1. Initial Page Load: When the user opens the page, the system automatically retrieves the full list of existing payment mappings and populates the "Store" and "Payment Type" dropdown menus with available options.
2. Data Display: The system presents the mapping data in a clear table format, showing the store name, the associated payment type, and whether that specific configuration is currently active.
3. Applying Filters: Users can narrow down the list by selecting specific stores, payment types, or active statuses from the dropdown menus.
4. Dynamic Updates: As soon as a filter is applied, the system instantly refreshes the table to display only the records that match the user's selected criteria.

2.3 Key Concepts

- Payment Type Mapping: The relationship between a specific store location and a payment method (e.g., Credit Card, Cash, or Digital Wallet) that is permitted for use at that location.
- Filtering: A tool that allows users to search or sort through large lists of data by selecting specific categories, such as viewing only "Active" payment types for a single "Store."
- Dropdown Options: Pre-defined lists of stores and payment types that ensure data consistency and make it easier for users to select valid criteria without manual entry.

2.4 Business Value

This feature streamlines financial setup by providing a clear, searchable view of payment configurations. By allowing users to easily filter and verify which payment methods are active at which stores, the business can reduce configuration errors, ensure compliance with store-specific payment policies, and simplify the administrative overhead of managing multi-store financial operations.

3. Data

3.1 Overview

The Payment Type Mapping feature allows the Lumi ERP system to organize and manage how different payment methods are associated with specific store locations. This tool provides a centralized view to track, enable, or disable these payment configurations, ensuring that the system correctly recognizes and processes payments based on the rules defined for each store.

3.2 Step-by-Step Flow

1. Data Retrieval: The system gathers all existing payment mapping rules and organizes them alphabetically by store name and payment type, making it easy for you to find specific records.
2. Information Display: These records are presented in a clear list view, showing which payment types are currently active for each store.
3. Status Management: If a payment method needs to be updated—such as toggling its active status or changing its details—you can modify the record directly.
4. System Synchronization: When updates are made, the system automatically records the time of the change, ensuring your audit trail is always up to date.
5. Data Translation: The system automatically translates incoming payment data from external sources into the internal format, ensuring that store names and payment types are correctly categorized without manual intervention.

3.3 Key Concepts

- Payment Type Mapping: A rule that links a specific payment method (like credit card or cash) to a particular store location.
- Active Status: A toggle that determines whether a specific payment method is currently available or "live" for a store.
- Data Transformation: The automated process of converting external information into the system's standard format to ensure consistency across all records.

3.4 Business Value

This feature simplifies financial administration by providing a single source of truth for payment configurations. By automating the mapping of payment types to stores, it reduces the risk of manual entry errors, ensures that financial reporting is accurate, and allows managers to quickly enable or disable payment methods across different locations as business needs change.

BUSINESS REQUIREMENTS DOCUMENT

Areas - Village

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Village" feature provides a centralized, easy-to-use interface for browsing and managing village data within the Lumi ERP system. Users can view a comprehensive list of villages, search for specific entries by name, and narrow down results using geographic filters (Province, Regency/Municipality, and District). The feature is designed to handle large datasets efficiently through pagination, ensuring the system remains responsive.

1.2 Step-by-Step Flow

1. Initial Load: When the user navigates to the Village page, the system automatically fetches and displays the first set of villages.
2. Applying Filters: The user can enter a specific village name or select geographic criteria (Province, Regency, or District) from the available dropdown menus to refine the list.
3. Executing Search: Upon clicking the "Search" button, the system applies the selected filters and refreshes the table to show only the matching results.
4. Navigating Results: If the list of villages spans multiple pages, the user can use the pagination controls at the bottom of the table to move between pages.
5. Viewing Details: Users can click on specific names within the table columns (Village, District, Regency, or Province) to navigate directly to the detailed information page for that specific entity.

1.3 Key Concepts

- Filtering: The ability to narrow down a large list of data by specific criteria, such as name or geographic location, to find information quickly.
- Pagination: A method of dividing a large dataset into smaller, manageable chunks (pages) to improve performance and readability.
- Geographic Hierarchy: The structured relationship between administrative areas (Province > Regency/Municipality > District > Village), which allows the system to provide relevant dropdown options based on previous selections.
- Data Table: A structured view that displays key information (Code, Name, and associated administrative regions) in a clear, organized format.

1.4 Business Value

- Improved Data Accessibility: By providing robust search and filter capabilities, staff can locate specific village information in seconds rather than scrolling through long lists.

- Operational Efficiency: The intuitive navigation between the village list and related administrative details (such as District or Province pages) streamlines the workflow for users managing regional data.
- System Performance: Pagination ensures that the application remains fast and responsive, even as the database grows to include thousands of village records.
- Data Accuracy: Standardized columns and clear identifiers (like the official village code) help users distinguish between villages with similar names, reducing the risk of data entry errors.

2. Logic

2.1 Overview

The "Village" feature in the Lumi ERP system provides a centralized way to view, search, and filter administrative village data. It allows users to browse a comprehensive list of villages and quickly narrow down results by location hierarchy (Province, Regency/Municipality, and District) or by specific name. The system is designed to handle large datasets efficiently by loading information in manageable chunks (pagination).

2.2 Step-by-Step Flow

1. Initial Load: When the user opens the Village page, the system automatically fetches the first page of the village list.
2. Filter Selection: The user can select a Province, which updates the available options for the Regency/Municipality dropdown. Selecting a Regency then updates the available options for the District dropdown.
3. Search Execution: The user enters a specific village name or selects location filters and clicks the "Search" button.
4. Data Retrieval: The system combines the user's search criteria and location filters to query the database. It retrieves the village name, code, and its associated district, regency, and province information.
5. Display: The results are presented in a table, showing only a set number of records at a time to ensure the page remains fast and easy to navigate.

2.3 Key Concepts

- Hierarchical Filtering: A cascading selection process where choosing a broader geographic area (like a Province) automatically limits the options available in the next level (Regency, then District).
- Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.
- Search Criteria: The specific parameters (name or location IDs) used to narrow down the master list of villages to only those that match the user's requirements.

- Data Integration: The system automatically links village records with their parent administrative entities (District, Regency, and Province) so that the user sees the full geographic context for every village in the list.

2.4 Business Value

- Improved Data Accuracy: By using hierarchical dropdowns, users are prevented from selecting invalid combinations of locations, ensuring data consistency.
- Enhanced Productivity: Users can quickly locate specific villages within large datasets without manual scrolling, saving time during administrative tasks.
- System Performance: Pagination ensures that the application remains responsive even as the number of villages in the database grows over time.

3. Data

3.1 Overview

The Village management feature allows users to easily browse, search, and filter through a comprehensive list of villages within the Lumi ERP system. By providing a clear view of the location hierarchy—including the village, district, regency, and province—this feature ensures that users can quickly locate specific administrative areas and manage location-based data effectively.

3.2 Step-by-Step Flow

1. Request Initiation: The user accesses the village list screen and applies optional search criteria, such as a specific village name or a location filter (Province, Regency, or District).
2. Parameter Processing: The system collects these search inputs, along with pagination settings (which determine how many results appear per page), to prepare a data request.
3. Data Retrieval: The system searches the database, linking the village information with its corresponding district, regency, and province to provide a complete geographical context.
4. Filtering: The system applies the user's specific filters to narrow down the results to only the relevant entries.
5. Display: The system returns the filtered, paginated list of villages, displaying the village code, name, and its full administrative hierarchy to the user.

3.3 Key Concepts

- Location Hierarchy: The structured relationship between administrative levels, where a village belongs to a district, which belongs to a regency, which belongs to a province.
-

Filtering: The ability to narrow down a large list of data by specific criteria, such as searching by name or selecting a specific administrative region.

- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve system performance and user readability.
- Administrative Mapping: The process of linking a village to its parent regions so that users can see the full "address" or location context of any given village.

3.4 Business Value

This feature streamlines administrative tasks by providing a centralized and searchable directory of villages. By integrating the full location hierarchy, it reduces manual data entry errors and helps users quickly verify location data. The inclusion of pagination and flexible filtering ensures that the system remains fast and responsive, even as the database grows, ultimately supporting more accurate reporting and organizational planning.

BUSINESS REQUIREMENTS DOCUMENT

Areas - Province

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Province Management feature provides a centralized interface for users to view, search, and navigate through a list of provinces within the Lumi ERP system. This feature ensures that users can quickly locate specific administrative areas and access their detailed information through a clean, organized table view.

1.2 Step-by-Step Flow

1. Authentication Check: Upon opening the page, the system verifies the user's login status. If the user is not logged in, they are automatically redirected to the login screen.
2. Initial Data Load: Once authenticated, the system automatically retrieves and displays the first page of provinces, sorted alphabetically by name.
3. Navigation: Users can switch between different administrative levels (Province, Regency/Municipality, District, and Village) using the tab menu at the top of the screen.
4. Searching: Users can enter a name into the search bar and click the "Search" button to filter the list. This action resets the view to the first page and displays only the results matching the search criteria.
5. Viewing Details: Each province name in the list is a clickable link. Selecting a province will navigate the user to a dedicated detail page for that specific area.

1.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can access the area management data.
- Filtering: The ability to narrow down the list of provinces by typing a specific name into the search field.
- Pagination: A method of organizing data into smaller, manageable pages to ensure the system remains fast and easy to read.
- Tab Navigation: A user interface element that allows for quick switching between different categories of administrative areas.

1.4 Business Value

This feature streamlines administrative data management by providing a consistent and efficient way to browse geographical information. By enabling quick search and clear navigation, it reduces the time staff spend looking up location data, minimizes manual errors, and ensures that users can easily transition from a high-level list to specific province details.

2. Logic

2.1 Overview

The Province management feature allows users to view, search, and navigate through a list of provinces within the Lumi ERP system. This feature ensures that only authenticated users can access the data and provides a streamlined interface to find specific provinces quickly using search and pagination tools.

2.2 Step-by-Step Flow

1. Session Verification: When a user accesses the page, the system automatically checks if they are logged in. If the session is invalid or expired, the user is redirected to the login screen.
2. Initial Data Load: Once authenticated, the system retrieves the first page of provinces, automatically sorted alphabetically by name.
3. Search Interaction: If a user types in the search bar, the system filters the list based on the input and resets the view to the first page of results.
4. Pagination: As the user navigates through different pages of the list, the system fetches and displays the corresponding set of provinces without losing the current search criteria.
5. Data Display: The system presents the province information in a clear table format, showing the unique ID, province code, name, and the date the record was created.

2.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can view sensitive business data.
- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down a large list of provinces by typing a specific name or code into a search field.
- Sorting: The automatic organization of data (in this case, by name in alphabetical order) to help users find information more efficiently.

2.4 Business Value

This feature provides a reliable and efficient way for staff to manage geographical data within the ERP. By implementing search and pagination, users can quickly locate specific provinces without scrolling through long lists, saving time and reducing manual effort. Furthermore, the built-in session validation ensures that company data remains secure by preventing unauthorized access.

3. Data

3.1 Overview

The Province management feature allows users to efficiently view, search, and navigate through the list of provinces stored in the Lumi ERP system. This tool is designed to help administrators quickly locate specific geographic areas by providing flexible search options and organized, manageable lists.

3.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view the list of provinces, which includes your preferred search terms and the specific page of results you wish to see.
2. Filtering: The system scans the province database to find matches based on the name or the unique province code you entered.
3. Pagination: To keep the information easy to read, the system breaks the results into smaller, manageable chunks (pages) based on your settings.
4. Data Retrieval: The system calculates the total number of provinces that match your search criteria and retrieves the specific set of records for the page you are currently viewing.
5. Display: The system presents the final list of provinces along with the total count, ensuring you know exactly how many results were found and which page you are on.

3.3 Key Concepts

- Search Filter: A tool that allows you to find a specific province by typing in its name or its unique identification code.
- Pagination: A method of displaying a large list of data across multiple pages, which prevents the screen from becoming cluttered and improves system performance.
- Province Code: A unique identifier assigned to each province to ensure there is no confusion between different geographic entries.
- Total Count: A summary figure that tells you how many provinces match your search, helping you understand the scope of your current view.

3.4 Business Value

This feature streamlines the setup process within the Lumi ERP by reducing the time spent manually scrolling through long lists. By providing robust search and pagination capabilities, users can maintain accurate geographic data with minimal effort, ensuring that province information is always accessible and easy to manage as the organization grows.

BUSINESS REQUIREMENTS DOCUMENT

Areas - Regency/Municipality

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Regency/Municipality feature provides a centralized interface within the Lumi ERP system to view, search, and manage administrative area data. Users can browse a comprehensive list of regencies and municipalities, filter them by specific criteria, and navigate through the data using pagination.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves the full list of provinces to populate the filter dropdown and fetches the initial page of regency data.
2. Filtering: Users can narrow down the list by typing a name into the search field or selecting a specific province from the dropdown menu.
3. Applying Search: Clicking the "Search" button triggers the system to refresh the table, displaying only the records that match the selected filters.
4. Navigation: Users can move through the list using the pagination controls at the bottom of the table. Each page change automatically updates the table view.
5. Drill-down: Users can click on a specific Regency or Province name within the table to navigate directly to that item's dedicated detail page.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down a large dataset based on specific criteria (such as name or province) to find relevant information quickly.
- Data Mapping: The process of connecting the system's internal data (like area codes and names) to the visual columns displayed in the table.
- Drill-down Navigation: A feature that allows users to click on a list item to view more comprehensive information about that specific record.

1.4 Business Value

This feature streamlines administrative tasks by providing a clean, searchable directory of regional data. By allowing users to filter by province and search by name, the system reduces the time spent manually looking up area information. Furthermore, the integrated navigation ensures that users can easily move between list views and specific detail pages, maintaining a smooth workflow within the ERP environment.

2. Logic

2.1 Overview

The Regency/Municipality management feature provides a centralized way to view, search, and filter administrative areas within the Lumi ERP system. Users can browse a comprehensive list of regencies and municipalities, narrow down results by specific provinces or names, and navigate through large datasets using pagination.

2.2 Step-by-Step Flow

1. Initial Load: When the page is first opened, the system automatically retrieves a list of all available provinces to populate the filter dropdown. Simultaneously, it loads the first page of regencies/municipalities (defaulting to 20 items).
2. Applying Filters: Users can refine the list by typing a name into the search bar or selecting a specific province from the dropdown menu.
3. Data Retrieval: Whenever a filter is applied or the user moves to a different page of results, the system sends a request to the server containing the current search criteria and pagination settings.
4. Display: The system receives the filtered data and displays it in a clear table format, showing the area code, the name of the regency or municipality, and the associated province.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down a large dataset based on specific criteria, such as searching by name or selecting a province.
- Province Lookup: An automated process that links each regency to its corresponding province name, ensuring the user sees clear, human-readable information in the list.

2.4 Business Value

This feature improves operational efficiency by allowing staff to quickly locate specific administrative regions without manually scrolling through long lists. By providing robust search and filter capabilities, the system ensures that data entry and reporting tasks involving geographic locations are accurate, consistent, and easy to manage.

3. Data

3.1 Overview

This feature provides a centralized management screen within the Lumi ERP system to view, search, and filter the list of regencies and municipalities. It allows users to quickly locate specific administrative areas by name or by narrowing down results to a specific province, ensuring that data is organized and easy to navigate through paginated lists.

3.2 Step-by-Step Flow

1. Load Province List: The system retrieves a complete list of provinces to populate the filter dropdown menu, allowing users to select a specific region.
2. Apply Filters: The user enters a search term (for a specific regency or municipality name) or selects a province from the dropdown.
3. Process Request: The system applies these filters to the database, searching for matching records while sorting them alphabetically by name.
4. Paginate Results: The system retrieves a specific "page" of results (e.g., 20 items at a time) to ensure the screen remains performant and easy to read.
5. Display Data: The system presents the final list to the user, showing the unique code, the name of the regency/municipality, and the associated province.

3.3 Key Concepts

- Regency/Municipality: The primary administrative divisions being managed in this module.
- Province: The larger administrative region used to categorize and filter the regencies.
- Filtering: The ability to narrow down the list of results based on specific criteria, such as name or province, to find information faster.
- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve system speed and user experience.

3.4 Business Value

- Improved Data Accuracy: By providing a clear view of all regencies and municipalities linked to their respective provinces, users can easily verify and manage administrative data.
- Increased Efficiency: Search and filter capabilities significantly reduce the time spent manually scrolling through long lists to find specific locations.
- Scalability: The use of pagination ensures that the system remains fast and responsive, even as the number of regencies and municipalities grows over time.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/vouchers

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get Vouchers" feature provides a secure way for authorized users to retrieve a list of vouchers from the Lumi ERP system. It includes flexible filtering and search capabilities, allowing users to pinpoint specific vouchers based on their type, status, or product details. The feature is designed to handle large datasets efficiently by allowing users to request specific "pages" of data.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is currently signed in. If the user is not authenticated, the request is rejected.
2. Parameter Processing: The system collects the user's search criteria (such as voucher type, status, or specific keywords) and validates them to ensure they meet system requirements.
3. Data Retrieval: If the parameters are valid, the system queries the database to find vouchers that match the provided filters.
4. Pagination: The system applies limits and offsets to the results, ensuring that only a manageable number of records are returned at one time.
5. Response: The system returns the requested list of vouchers. If an error occurs during the process (such as invalid input or a server issue), the system provides an appropriate error message.

1.3 Key Concepts

- Filtering: The ability to narrow down the list of vouchers by specific attributes like `voucher_type` (standard, batch, or flexible) or `status` (active, inactive, or expired).
- Search: A keyword-based search that scans both the Product SKU and the Product Name to help users find relevant vouchers quickly.
- Pagination: A method of breaking large lists into smaller, manageable chunks using `limit` (how many items to show) and `offset` (how many items to skip).
- Authentication: A security gate that ensures only signed-in users can access voucher data.

1.4 Business Value

This feature empowers users to manage and audit vouchers effectively within the Lumi ERP. By providing robust search and filter options, it reduces the time spent manually looking for specific records. Furthermore, the inclusion of pagination ensures that the system remains performant and responsive, even as the number of vouchers in the database grows over time.

2. Data

2.1 Overview

The `GET /api/vouchers` feature provides a way for users to retrieve a list of vouchers from the Lumi ERP system. It is designed to be flexible, allowing users to narrow down large lists of vouchers using specific filters or a general search, and to manage how much data is returned at once through pagination.

2.2 Step-by-Step Flow

1. Request Initiation: The user sends a request to view the voucher list. They can optionally include filters (such as voucher type, status, or specific product identifiers) and pagination settings.
2. Data Filtering: The system processes the request by applying any provided filters to the voucher database. It also performs a search across product names and SKUs if a search term is provided.
3. Sorting: The system automatically sorts the resulting list by the date the vouchers were created, showing the most recent ones first.
4. Pagination: The system applies the requested limit (how many items to show) and offset (how many items to skip) to ensure the response is manageable.
5. Data Formatting: The retrieved records are organized into a standardized format that includes the voucher details and a count of the total items returned.
6. Response: The system returns the final list to the user. If the request is invalid, the user is not logged in, or a system error occurs, the system returns an appropriate error message.

2.3 Key Concepts

- Filters: Specific criteria used to narrow down results, such as `voucher_type` (standard, batch, or flexible) or `status` (active, inactive, or expired).
- Search: A broad lookup tool that scans both the Product SKU and Product Name fields for a matching keyword.
- Pagination: A method to break large lists into smaller, readable chunks using a `limit` (number of items per page) and `offset` (starting point in the list).
- Data Mapping: The process of ensuring that the information pulled from the database is presented in a consistent, predictable format for the user.

2.4 Business Value

This feature enables efficient management of voucher inventory by allowing staff to quickly locate specific vouchers without manually scrolling through the entire database. By supporting flexible filtering and pagination, the

system remains performant and user-friendly, even as the volume of vouchers grows. This ensures that business operations—such as checking the status of a batch or verifying a specific product voucher—can be performed accurately and in real-time.

BUSINESS REQUIREMENTS DOCUMENT

New Product Brand Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The New Product Brand Modal is a pop-up window designed to help users quickly add a new brand to the system while working within the product management pages. It provides a simple, guided interface to input brand details, ensuring that all necessary information is captured correctly before the new brand is saved to the database.

1.2 Step-by-Step Flow

1. Open the Modal: The user initiates the action to create a new brand, triggering the "New Product Brand" window.
2. Enter Brand Name: The user types the name of the brand into the required "Name" field. The system checks this input in real-time to ensure it is not left blank.
3. Enter Description (Optional): The user may optionally provide a brief description of the brand in the provided text area.
4. Validation: As the user types, the system monitors the input. If the "Name" field is empty, the "Save" button remains disabled to prevent incomplete data from being submitted.
5. Save or Cancel:

* If the user clicks "Save," the system validates the data one final time and creates the new brand. Upon success, the modal closes.
* If the user clicks "Cancel" or the close icon, the modal closes immediately, and no information is saved.

1.3 Key Concepts

- Modal: A focused window that appears on top of the current page, allowing users to complete a specific task without navigating away from their current work.
- Real-time Validation: A feature that checks the information entered by the user immediately, providing instant feedback if a required field is missing.
- Required Field: A specific piece of information (in this case, the Brand Name) that must be provided before the system will allow the user to proceed.
- Submission Handling: The process where the system verifies the final input and communicates with the server to officially record the new brand.

1.4 Business Value

This feature streamlines the product management workflow by allowing users to define new brands on the fly. By including built-in validation, the system prevents data entry errors and ensures that all new brands are created

with the necessary information, maintaining high data quality across the ERP system without requiring the user to leave their current task.

2. LOGIC

2.1 Overview

The New Product Brand Modal is a feature designed to help users quickly add a new brand while they are in the process of creating or editing a product. Instead of navigating away from their current task, users can open this pop-up window, enter the brand details, and save them directly to the system.

2.2 Step-by-Step Flow

1. Input Validation: When the user clicks "Save," the system checks that a brand name has been provided. If the name field is empty, the system alerts the user and keeps the window open so they can fix the error.
2. Data Submission: If the information is valid, the system sends the brand name and optional description to the database.
3. Success Processing: Once the brand is successfully created, the system automatically adds the new brand to the product selection list, selects it for the current product, and updates the master list of brands.
4. Closing: The modal window closes automatically, returning the user to their previous screen.
5. Error Handling: If the system encounters an issue (such as a duplicate name), it will display a specific error message under the name field to guide the user on how to resolve the problem.

2.3 Key Concepts

- Validation: A safety check that ensures required information is present before the system attempts to save data.
- Modal: A pop-up window that allows users to perform a specific task without leaving the page they are currently working on.
- Dynamic Update: The ability of the system to refresh lists and selections automatically so the user sees their new brand immediately without needing to refresh the entire page.

2.4 Business Value

This feature improves efficiency by reducing "context switching." By allowing users to create new brands on the fly, they can complete their product entries in a single, uninterrupted workflow. This minimizes data entry friction and ensures that the product catalog remains accurate and up-to-date without requiring the user to navigate to a separate administrative settings page.

BUSINESS REQUIREMENTS DOCUMENT

New Product Tag Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The New Product Tag Modal is a user-friendly pop-up window designed to help staff quickly create and categorize products within the Lumi ERP system. This feature allows users to define a new tag name and an optional description directly from the product management screens, ensuring that product organization remains consistent and efficient without needing to navigate away from their current task.

1.2 Step-by-Step Flow

1. Open the Modal: The user initiates the process from the product page, triggering the "New Product Tag" window.
2. Enter Details: The user provides a name for the tag (required) and an optional description.
3. Validation: As the user types, the system checks that the required "Name" field is filled. If the user attempts to save without a name, the system will highlight the error.
4. Save or Cancel:

* Save: The system verifies the input, creates the new tag in the database, and closes the window upon success.

* Cancel: The user can close the window at any time using the "Cancel" button or the close icon, which discards any unsaved information.

1.3 Key Concepts

- Modal: A pop-up window that appears over the main screen, allowing users to complete a specific task without leaving their current page.
- Validation: An automated check that ensures essential information (like the tag name) is provided before the system accepts the data.
- Mutation: The background process that sends the new tag information to the system's database to be permanently stored.

1.4 Business Value

This feature streamlines the product management workflow by reducing the number of clicks and page transitions required to organize inventory. By allowing users to create tags on the fly, the system promotes better data hygiene and more accurate product categorization, which ultimately leads to improved searchability and reporting capabilities within the ERP.

2. Logic

2.1 Overview

The New Product Tag Modal is a feature designed to streamline the product management process. It allows users to create new product tags directly from the "Add" or "Edit" product pages without needing to navigate away to a separate settings screen. This ensures that users can categorize their products efficiently while maintaining their current workflow.

2.2 Step-by-Step Flow

1. Input Validation: When you click the "Save" button, the system first checks that a name has been entered for the tag. If the name field is empty, the system will display an error message and keep the modal open so you can correct it.
2. Submission: If the name is valid, the system sends the tag name and its optional description to the database to be created.
3. Success Handling: Once the tag is successfully created, the system automatically adds it to your existing list of tags, selects it for the product you are currently editing, and refreshes the list to ensure everything is up to date.
4. Closing: After the tag is successfully processed and selected, the modal closes automatically, returning you to the main product page.
5. Error Handling: If an unexpected issue occurs during the process, the system will display an error message to inform you that the action could not be completed.

2.3 Key Concepts

- Product Tag: A label used to categorize products, making them easier to organize and search within the system.
- Validation: A safety check that ensures required information (like the tag name) is provided before the system attempts to save data.
- Modal: A pop-up window that allows you to perform a specific task (like creating a tag) without leaving the page you are currently working on.
- State Management: The system's ability to automatically update the background page (the tag list and selector) so that your new tag is immediately available for use without requiring a manual page refresh.

2.4 Business Value

This feature improves user productivity by reducing the number of clicks and page transitions required to manage product metadata. By allowing users to create tags "in the moment," it minimizes workflow interruptions and

ensures that product categorization remains consistent and up-to-date, ultimately leading to better-organized inventory data.

BUSINESS REQUIREMENTS DOCUMENT

New Service Product Type Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Service Product Type" modal is a user-friendly pop-up window designed to help staff quickly categorize service offerings within the Lumi ERP system. By providing a dedicated space to define new service types, this feature ensures that users can maintain an organized service catalog without leaving their current workflow.

1.2 Step-by-Step Flow

1. Open the Modal: The user initiates the process from the main service product page, triggering the "New Service Product Type" window.
2. Enter Details: The user provides a name for the new service type (which is mandatory) and an optional description to provide further context.
3. Real-time Validation: As the user types, the system checks that the name field is not left empty. If the name is missing, the system alerts the user immediately.
4. Submission: Once the required information is entered, the user clicks the "Save" button to finalize the creation of the new service type.
5. Completion or Cancellation: Upon a successful save, the modal closes automatically. Alternatively, the user can click "Cancel" or the "X" icon at any time to discard their changes and close the window without saving.

1.3 Key Concepts

- Service Product Type: A classification label used to group similar services together, making it easier to manage and report on service offerings.
- Validation: An automated check that ensures essential information (the name) is provided before the system accepts the new entry.
- Modal: A focused window that appears on top of the main screen, allowing users to complete a specific task without navigating away from their current page.
- Active Status: By default, all new service types are set to "active," meaning they are immediately available for use in the system upon creation.

1.4 Business Value

This feature streamlines the administrative process of managing service catalogs. By allowing users to create new categories on the fly, it reduces manual data entry friction and ensures that the service product list remains accurate and up-to-date. This consistency helps improve reporting accuracy and ensures that all services are properly categorized for better business insights.

2. Logic

2.1 Overview

The "New Service Product Type" modal is a streamlined tool designed to help users quickly define and categorize new service offerings within the Lumi ERP system. By providing a dedicated interface for this task, users can add new service types directly from the service product page without navigating away from their current workflow.

2.2 Step-by-Step Flow

1. Input Entry: The user opens the modal and enters the required details, specifically the name of the service type, an optional description, and its active status.
2. Validation: Upon clicking "Save," the system checks to ensure the mandatory name field is filled out.
3. Submission: If the information is valid, the system securely sends the data to the database to create the new entry.
4. Confirmation: Once the system successfully saves the new service type, the modal automatically closes, and the application updates to reflect the new addition.
5. Error Handling: If the submission fails (e.g., due to missing information or a system error), the modal remains open and displays a clear message explaining what went wrong so the user can correct it.

2.3 Key Concepts

- Service Product Type: A category or classification used to organize different types of services offered by the business.
- Modal: A pop-up window that allows users to perform a specific task (like creating a new item) without leaving the main page they are currently viewing.
- Validation: A safety check performed by the system to ensure that all required information is provided before attempting to save data.
- Active Status: A setting that determines whether a service type is currently available for use within the system.

2.4 Business Value

This feature improves operational efficiency by reducing the time and effort required to manage service catalogs. By allowing users to create new service types on the fly, the system ensures that the ERP remains up-to-date with the latest service offerings, leading to more accurate reporting and smoother service management processes.

BUSINESS REQUIREMENTS DOCUMENT

New Service Product Tags Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Service Product Tag" modal is a streamlined tool designed to help users categorize service products directly within the "Add Service Product" page. This feature allows staff to quickly define new tags—such as specific service types or categories—without navigating away from their current workflow, ensuring that product data remains organized and consistent.

1.2 Step-by-Step Flow

1. Open the Modal: The user initiates the process from the "Add Service Product" page, opening the "New Service Product Tag" window.
2. Enter Tag Details: The user provides a name for the tag (which is mandatory) and an optional description to provide further context.
3. Validation: The system ensures the name is provided and adheres to length requirements.
4. Submit or Cancel:

* If the user clicks Save, the system attempts to create the new tag. Upon success, the modal closes and the new tag becomes available for use.
* If the user clicks Cancel or the Close (X) icon, the modal closes immediately, and any entered information is discarded.

1.3 Key Concepts

- Service Product Tag: A label used to categorize or group service products, making them easier to filter and manage within the ERP system.
- Modal: A pop-up window that appears over the main screen, allowing the user to complete a specific task without leaving their current page.
- Validation: A built-in check that ensures required information (like the tag name) is present and formatted correctly before the system accepts the data.

1.4 Business Value

- Improved Efficiency: Users can create new tags on the fly, preventing interruptions to their data entry process.
- Data Consistency: By providing a simple interface for tag creation, the system encourages users to categorize products accurately, which leads to better reporting and easier product discovery.
- Reduced Friction: The intuitive design minimizes the time spent managing administrative settings, allowing staff to focus on core service product management.

2. Logic

2.1 Overview

The New Service Product Tags Modal is a feature designed to help users quickly create and categorize service products directly within the "Add Service Product" page. Instead of navigating away to a separate settings page, users can open this modal to define a new tag name and description, which is then immediately available for use in their current task.

2.2 Step-by-Step Flow

1. Input Details: The user enters a name and an optional description for the new tag into the modal form.
2. Validation: When the user clicks "Save," the system checks that a name has been provided. If the name field is empty, an error message appears to prompt the user for the required information.
3. Submission: Once validated, the system securely sends the new tag information to the database.
4. Confirmation and Update: Upon a successful save, the system receives confirmation and the new tag's unique ID. The modal automatically closes, and the new tag is instantly added to the service product dropdown menu and selected for the user.

2.3 Key Concepts

- Service Product Tag: A label used to categorize and organize service products, making them easier to find and manage.
- Validation: A built-in check that ensures essential information (the tag name) is provided before the system attempts to save the data.
- Modal: A pop-up window that allows users to perform a specific task—in this case, creating a tag—without leaving the page they are currently working on.

2.4 Business Value

This feature improves user efficiency by streamlining the workflow. By allowing users to create tags "on the fly" while adding a service product, it eliminates the need to interrupt their work to navigate to a different part of the application. This reduces friction, saves time, and ensures that product categorization remains consistent and up-to-date.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Vehicles

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Frontend

1.1 Overview

The Customer Vehicles page provides a centralized view for managing and searching the fleet of vehicles associated with your customers. This feature allows users to quickly locate specific vehicles using various search criteria and status filters, ensuring that information regarding vehicle ownership, service contracts, and registration details is easily accessible.

1.2 Step-by-Step Flow

1. Page Initialization: When the page loads, the system automatically retrieves and displays all "Active" vehicles.
2. Status Filtering: Users can toggle between "Active" and "Inactive" tabs to instantly update the list based on the vehicle's current status.
3. Advanced Search: Users can narrow down the list by entering specific details such as Customer name, Hull Number, Registration Number, or VIN.
4. Categorical Filtering: Users can further refine results by selecting a specific Vehicle Type (e.g., Car, Motorcycle, Heavy Equipment) or a specific Store location.
5. Date Range Filtering: Users can select a date type (Created Date or Registration Date) and define a "From" and "To" date range to isolate records within a specific timeframe.
6. Applying Filters: After setting the desired criteria, clicking the "Search" button refreshes the table to show only the matching records.
7. Data Export: A "Download" button is available to export the currently filtered list for external reporting or record-keeping.
8. Navigation: Clicking on any row in the vehicle table will navigate the user directly to the details page for that specific customer.

1.3 Key Concepts

- Active/Inactive Status: A toggle that filters the list to show only currently operational vehicles or those that have been archived/deactivated.
- Search Filters: A set of input fields and dropdowns that allow users to query the database for specific vehicles based on unique identifiers or categories.
- Date Range: A flexible filter that allows users to search for vehicles based on when they were created or registered.
-

Data Table: The main display area that organizes vehicle information into columns, such as Make, Model, Year, and Service Contract, for easy comparison.

- Row Redirection: A navigation feature where clicking a vehicle record takes the user to the associated customer's profile.

1.4 Business Value

This feature streamlines customer management by reducing the time spent searching for vehicle records. By providing granular filtering options, staff can quickly verify service contracts, check registration details, or identify vehicle ownership, leading to more efficient customer service and improved operational oversight of the fleet.

2. Logic

2.1 Overview

The Customer Vehicles page provides a centralized view of all vehicle records within the Lumi ERP system. To help users manage their fleet efficiently, the page includes a status-based filtering system that allows you to toggle between active and inactive vehicles. By default, the page loads with the "Active" filter applied, ensuring you see the most relevant information immediately upon arrival.

2.2 Step-by-Step Flow

1. Initial Load: When you first open the page, the system automatically retrieves and displays all vehicles currently marked as "Active."
2. Filtering: You can switch between "Active" and "Inactive" views using the status tabs provided above the vehicle table.
3. Data Retrieval: Whenever you select a tab, the system sends a request to the database to fetch only the vehicles matching that specific status.
4. Display: The table updates to show the relevant vehicle details, including registration numbers, make, model, customer association, and service contract information.

2.3 Key Concepts

- Status Filter: A toggle mechanism that restricts the list of vehicles based on their current operational status (Active vs. Inactive).
- Vehicle Details: The comprehensive set of information displayed for each record, such as identification numbers (VIN/FIN), physical descriptions (make/model/year), and business context (assigned customer, store location, and service contract).
- Default View: The pre-configured state of the page that prioritizes active records to streamline daily operations.

2.4 Business Value

This feature improves operational efficiency by allowing staff to quickly isolate active fleet assets from inactive ones. By providing a clean, filtered view, users can reduce clutter, focus on current service contracts and customer assignments, and easily manage the lifecycle of vehicles within the ERP without manually sorting through historical or retired data.

3. Data

3.1 Overview

The Customer Vehicles feature provides a centralized view within the Lumi ERP system to manage and track vehicle information. This page allows users to see a comprehensive list of vehicles associated with customers, including key identification details, service contract information, and the store location. To help users focus on relevant information, the page includes a filtering capability to display only vehicles with a specific status.

3.2 Step-by-Step Flow

1. Request: The user accesses the vehicle list page, optionally selecting a specific status filter (e.g., "Active").
2. Data Retrieval: The system gathers vehicle records, automatically linking each vehicle to its corresponding customer, service contract, and store location.
3. Filtering: If a status filter was selected, the system narrows the list to show only those vehicles; otherwise, it displays the full list.
4. Sorting: The system organizes the final list by the date the vehicle record was created, showing the most recently added vehicles at the top.
5. Display: The information is presented in a clear table format, showing details such as registration number, make, model, year, and associated business entities.

3.3 Key Concepts

- Vehicle Status: A label assigned to a vehicle that allows users to categorize them (e.g., Active, Inactive) and filter the list accordingly.
- Linked Entities: The system automatically connects vehicle records to other important business data, such as the assigned Customer, the active Service Contract, and the responsible Store.
- Identification Details: Specific identifiers—such as Registration Number, VIN (Vehicle Identification Number), and FIN (Fleet Identification Number)—that ensure each vehicle is uniquely and accurately tracked.

3.4 Business Value

This feature improves operational efficiency by providing a single source of truth for the vehicle fleet. By allowing users to filter by status, staff can quickly identify active assets, reducing the time spent searching through records. Furthermore, by linking vehicles directly to customers, service contracts, and stores, the system ensures that support teams and managers have immediate access to the context needed to provide better customer service and manage maintenance agreements effectively.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Franchise List Page

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Frontend

1.1 Overview

The Franchise List Page provides a centralized view for managing franchise customer records within the Lumi ERP system. This page allows users to view a comprehensive list of franchisees, search for specific records using various criteria, and perform quick administrative actions like editing or deactivating a franchise account.

1.2 Step-by-Step Flow

1. Initial Load: When the page is first opened, the system automatically retrieves and displays the full list of available franchises.
2. Filtering: Users can narrow down the list using the filter bar. You can search by specific details such as customer group, store, active status, code, tax number, birthdate, phone, or address.
3. Applying Search: Once the desired filters are entered, clicking the "Apply Search" button triggers the system to refresh the table, showing only the records that match the criteria provided.
4. Viewing Details: Users can click on a franchisee's name or their unique franchise code to navigate directly to that specific customer's detailed record.
5. Managing Records: Each row includes action buttons to either edit the franchisee's information or deactivate the account. If "Deactivate" is selected, a confirmation window appears to prevent accidental changes.

1.3 Key Concepts

- Filter Bar: A set of search fields that allows users to find specific franchisees without needing to scroll through the entire list. Only fields with information entered are used to refine the search.
- Franchise Table: The main display area that organizes franchisee data into columns, including contact information, status, and geographic region.
- Action Buttons: Tools located on each row that allow for quick updates (Edit) or status changes (Deactivate) for individual franchisees.
- Deactivation Modal: A safety feature that requires a user to confirm their intent before an account status is changed to "Inactive."

1.4 Business Value

This feature streamlines franchise management by providing a high-level overview of all franchise partners in one place. By enabling quick filtering and direct access to individual records, staff can spend less time searching for data and more time managing relationships. Additionally, the built-in deactivation workflow ensures that status changes are intentional and accurate, maintaining data integrity across the ERP.

2. Logic

2.1 Overview

The Franchise List Page is a dedicated interface within the Lumi ERP system designed to help users manage and view franchise-specific customer data. This feature allows users to instantly view a list of all franchise customers upon opening the page, search for specific records using various criteria, and manage the status of these customers by deactivating them when necessary.

2.2 Step-by-Step Flow

1. Initial Load: When the page is opened, the system automatically retrieves the full list of franchise customers and displays them in the list view.
2. Data Mapping: The system organizes the raw customer information into the user interface, ensuring details like the customer's name, franchise code, contact information, and current status are clearly visible.
3. Filtering: Users can narrow down the list by entering information into the filter bar (such as customer group, store, tax number, or contact details). When the user clicks "Apply," the system sends only the active search criteria to the server to fetch the relevant results.
4. Deactivation: If a user needs to remove a franchise customer from active status, they can click the "Deactivate" button. This triggers a confirmation process, after which the system updates the customer's status to "Inactive" in the database.

2.3 Key Concepts

- Franchise Customer: A specific category of customer within the ERP system that requires unique tracking, such as a franchise code and regional assignment.
- Filter Bar: A search tool that allows users to find specific records by applying one or more criteria (e.g., searching by phone number or tax ID) without needing to browse the entire list.
- Status Management: The ability to toggle a customer's state to "Inactive," which helps maintain accurate records without permanently deleting historical data.
- Data Mapping: The process of taking raw information from the system's database and placing it into the correct fields on the screen so it is easy for the user to read.

2.4 Business Value

This feature streamlines franchise management by providing a centralized, searchable view of all franchise-related customers. By enabling quick filtering and simple status updates, it reduces the administrative burden on staff,

ensures that customer records remain accurate and up-to-date, and allows for faster decision-making when managing franchise relationships.

3. Data

3.1 Overview

The Franchise List Page feature provides a dedicated view within the Lumi ERP system to manage and monitor franchise-specific customer accounts. This tool allows users to quickly locate franchises, filter them by their current operational status, and view their relationship to parent corporate entities, ensuring clear oversight of the franchise network.

3.2 Step-by-Step Flow

1. Requesting the List: The system retrieves all customers categorized specifically as "Franchises."
2. Applying Filters: Users can narrow down the list by searching for a specific franchise name or by selecting a status (such as Active or Inactive).
3. Sorting: The results are automatically organized to show the most recently created franchises at the top of the list.
4. Viewing Details: When a user selects a specific franchise, the system displays its profile, including its official name, current status, registration date, and the name of its parent corporate organization.

3.3 Key Concepts

- Franchise: A specific type of customer account within the ERP that operates under a parent corporate entity.
- Status Filtering: A tool that allows users to isolate franchises based on their operational state, helping to manage active versus inactive locations.
- Parent Organization: The corporate entity that oversees or owns the franchise, providing context on the business hierarchy.
- Data Mapping: The process of translating raw system information into a clear, user-friendly format for the dashboard.

3.4 Business Value

This feature streamlines administrative tasks by providing a centralized hub for franchise management. By enabling quick searches and status-based filtering, staff can spend less time hunting for records and more time managing relationships. Additionally, by clearly linking franchises to their parent organizations, the system ensures that users have the necessary context to make informed decisions regarding corporate compliance and account management.

BUSINESS REQUIREMENTS DOCUMENT

Customers - Retail Customers List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Retail Customers List page provides a centralized dashboard for managing your retail customer base. It allows you to view a comprehensive list of customers, search for specific individuals using various criteria, and navigate to detailed customer profiles or create new entries.

1.2 Step-by-Step Flow

1. Initial Load: When you open the page, the system automatically retrieves and displays all retail customers.
2. Filtering: You can narrow down the list by entering information into the filter bar (such as Name, Phone, Tax Number, or Customer Group).
3. Search Execution: Once you have entered your desired criteria, click the "Apply Search" button. The system will refresh the table to show only the customers that match your specific filters.
4. Navigation: You can switch between different customer categories (Retail, Wholesale, or Franchisee) using the navigation tabs at the top of the page.
5. Customer Management:

- Click on any row in the table to view the full details for that specific customer.
- Click the "Add New Retail Customer" button to create a new record.
- Use the "Deactivate" button within the table to open a confirmation window for removing a customer's active status.

1.3 Key Concepts

- Filter Bar: A set of input fields that allows you to refine the customer list based on specific data points like status, contact information, or location.
- Retail Customer Type: The system specifically targets retail-type customers for this view, ensuring you are only seeing the relevant segment of your database.
- Data Table: The main display area that organizes customer information into columns (such as ID, Name, Email, and Store) for easy readability.
- Sorting: You can click on specific column headers (like Name or Code) to organize the list alphabetically or numerically to find information faster.
- Deactivation: A safety feature that requires a confirmation step before changing a customer's status to "inactive," preventing accidental updates.

1.4 Business Value

This feature streamlines daily operations by providing a fast, searchable interface for customer data. By allowing staff to quickly filter by specific attributes—such as tax numbers or store locations—the system reduces the time spent searching for records. Additionally, the ability to easily navigate between customer types and manage status updates directly from the list page improves overall data accuracy and administrative efficiency.

2. Logic

2.1 Overview

The Retail Customers List page is designed to provide a centralized view for managing retail customer data. This feature allows users to browse, search, and filter customer records efficiently. By using specific criteria—such as customer groups, regions, or general search terms—users can quickly locate the information they need, which is then displayed in a clear, organized table format.

2.2 Step-by-Step Flow

1. Initiate Request: When the page loads or when a user applies search/filter criteria, the system sends a request to retrieve the relevant retail customer data.
2. Apply Filters: The system includes the user's selected filters (such as search text, customer group, region, or page number) to ensure the results are specific to the user's needs.
3. Retrieve Data: The system fetches the customer information from the database based on the provided criteria.
4. Format Data: The raw data is processed and mapped into a user-friendly table structure, ensuring that details like contact information, store location, and account status are correctly aligned with the table columns.
5. Display Results: The final, formatted list is rendered on the screen, allowing the user to view the updated customer information.

2.3 Key Concepts

- Filters: Tools that allow users to narrow down the customer list by specific categories like region, group, or keyword searches.
- Pagination: A method of breaking the customer list into smaller, manageable pages to improve performance and readability.
- Data Mapping: The process of taking raw system information and organizing it into the specific columns shown in the table (e.g., ensuring the "email" field appears in the "Email" column).
- Customer Status: A visual indicator or action that shows whether a customer account is currently active.

2.4 Business Value

This feature streamlines daily operations by reducing the time spent searching for customer records. By providing robust filtering and a clear, structured view, staff can quickly access accurate customer details, improve response times for customer inquiries, and maintain better oversight of the retail customer base.

3. Data

3.1 Overview

The Retail Customers List page is a centralized dashboard designed to help you efficiently manage and view your customer base. It provides a clear, organized view of all retail customers, allowing you to quickly locate specific individuals or groups using flexible search and filtering tools. The page is designed to handle large volumes of data by breaking the list into manageable pages, ensuring the system remains fast and easy to navigate.

3.2 Step-by-Step Flow

1. Define Search and Filters: You enter your criteria, such as a customer's name, email, or unique code. You can also narrow down the list by selecting specific customer groups, geographic regions, or by toggling between active and inactive customer statuses.
2. Data Retrieval: The system processes your request, applying these filters to the database to find only the relevant records.
3. Pagination: The system organizes the results into pages (e.g., 20 or 50 customers per page) so you aren't overwhelmed by a single long list.
4. Display: The filtered data is presented in a clean table format, showing key details like contact information, assigned store, and current status for each customer.

3.3 Key Concepts

- Pagination: A method of splitting a large list of data into smaller, separate pages to improve performance and readability.
- Filtering: The ability to narrow down the list of customers based on specific attributes like their region, group, or active status.
- Search Query: A text-based search that scans customer names, emails, and codes to find a specific match instantly.
- Customer Status: A toggleable indicator that identifies whether a customer is currently active or inactive within the system.

3.4 Business Value

-

Improved Productivity: Staff can quickly find the information they need without scrolling through thousands of records.

- Better Data Organization: By grouping and filtering customers by region or status, managers can gain clearer insights into their customer base.
- Scalability: The use of pagination ensures that the system remains responsive and fast, even as your customer list grows over time.
- Accuracy: Standardized mapping of customer details ensures that every user sees consistent, reliable information across the entire platform.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Wholesale Customer List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Wholesale Customer List feature provides a centralized dashboard for managing wholesale business accounts. It allows users to view a comprehensive list of customers, search for specific records using various criteria, and perform quick administrative actions like deactivating accounts. The interface is designed to help sales and administrative teams efficiently locate and manage customer information.

1.2 Step-by-Step Flow

1. Initial Load: When the page opens, the system automatically retrieves and displays the first page of wholesale customers.
2. Filtering: Users can narrow down the list by entering criteria into the filter bar (such as Name, Code, Group, or Salesperson) or by using the "Address Filter" popup for location-based searches.
3. Search Execution: Once the desired filters are set, clicking the "Search" button updates the table to show only the matching results.
4. Navigation: Users can click on any row in the table to view the full details of a specific customer.
5. Pagination: If the list is long, users can navigate through multiple pages using the pagination controls at the bottom of the screen.
6. Account Management: Users can click the "Deactivate" button on any row to open a confirmation window to change the status of a customer account.

1.3 Key Concepts

- Filter Bar: A set of input fields that allows users to refine the customer list based on specific data points like tax numbers, birthdates, or active status.
- Address Filter: A specialized tool that allows for granular location-based searching, ranging from broad regions down to specific street addresses.
- Pagination: A navigation system that breaks large lists into smaller, manageable pages to ensure the application remains fast and easy to read.
- Customer Detail View: A dedicated page for a specific customer, accessed by clicking their name or row in the main list.
- Deactivation: A status management action that allows users to mark a customer as inactive without deleting their record from the system.

1.4 Business Value

This feature streamlines wholesale operations by providing a "single source of truth" for customer data. By enabling quick filtering and direct access to customer details, staff can reduce the time spent searching for records. Additionally, the ability to manage account status (active/inactive) directly from the list view ensures that customer records remain accurate and up-to-date, supporting better sales tracking and account management.

2. Logic

2.1 Overview

The Wholesale Customer List feature provides a dedicated view within the Lumi ERP system to help your team manage and track business-to-business (wholesale) clients. This tool automatically filters your entire customer database to display only those categorized as "Wholesale," ensuring that sales and account management teams have quick access to the specific information they need to support these high-volume accounts.

2.2 Step-by-Step Flow

1. The system scans the master customer database.
2. It applies a filter to isolate only those records marked as part of the "Wholesale" customer group.
3. The system gathers the relevant details for each identified wholesale customer, including their contact information, assigned salesperson, and current account status.
4. This organized list is then presented to the user, providing a clear overview of all active and inactive wholesale accounts.

2.3 Key Concepts

- Wholesale Segment: A specific classification used to distinguish high-volume or business-to-business clients from standard retail customers.
- Account Status: A toggle indicating whether a customer account is currently active or inactive, allowing for better management of your client list.
- Assigned Salesperson: The specific staff member responsible for managing the relationship with a particular wholesale account.
- Customer Profile Data: The collection of identifying details—such as name, region, and contact information—that allows your team to effectively communicate with and service these clients.

2.4 Business Value

This feature streamlines operations by eliminating the need to manually sort through your entire customer base to find wholesale partners. By providing a clean, focused list, your team can improve response times, ensure that

account management responsibilities are clear, and maintain accurate records for your most important business relationships.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Franchisee Customers Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchisee Customer Detail Page provides a centralized, read-only view of a specific franchisee customer's profile within the Lumi ERP system. This page allows staff to quickly review essential business information, tax details, pricing, and account settings for a selected customer, ensuring that all relevant data is easily accessible in one location.

1.2 Step-by-Step Flow

1. Loading Data: When a user selects a specific customer, the system automatically retrieves that customer's full profile from the database.
2. Navigation & Context: The page displays a navigation bar and sub-menu to keep the user oriented within the "Customers" section. A "Customer" button is available to return the user to the main customer list at any time.
3. Header Display: The page header prominently displays the customer's name and provides an "Edit" button for users who need to update the information.
4. Information Layout: The customer's data is organized into specific, logical sections (cards) for easy reading:

* Details: Core identity, contact information, and assigned salesperson.

* Customer Group: The specific group classification for the customer.

* Tax Information: Essential tax identifiers and registration numbers.

* Settings: Account status, credit terms, and specific business flags (e.g., franchise or wholesale status).

* Prices: The specific price list assigned to this customer.

* Data Mapping: A summary of the salesperson assigned to the account.

* Changes: An audit trail showing when the record was created or updated and by whom.

5. Tab Navigation: A dedicated tab menu allows the user to switch between different customer-related views (such as Retail Customers) without leaving the context of the franchisee menu.

1.3 Key Concepts

– Read-Only View: A display mode where information is presented for review without allowing direct changes, ensuring data integrity until the "Edit" function is triggered.
– Audit Trail: A record of "Changes" that tracks the history of the customer profile, including timestamps and the users responsible for creating or modifying the data.
–

Data Mapping: The process of organizing raw system data into clear, labeled categories (cards) so that users can find specific information like tax IDs or credit terms quickly.

– Franchisee Context: The specific business logic that filters and displays information relevant to franchise-based customer relationships.

1.4 Business Value

This feature improves operational efficiency by eliminating the need to search through multiple screens to find customer information. By consolidating identity, tax, pricing, and account history into a single, well-organized view, staff can make faster, more informed decisions regarding customer management and support. The inclusion of an audit trail also enhances accountability and transparency by clearly showing the history of any updates made to a customer's profile.

2. Logic

2.1 Overview

The Franchisee Customer Detail page provides a comprehensive, read-only view of a specific customer's profile within the Lumi ERP system. When a user navigates to this page, the system automatically retrieves all relevant information for that customer and organizes it into logical sections, allowing staff to quickly review account details, tax information, credit terms, and administrative history.

2.2 Step-by-Step Flow

1. Page Initialization: When the page is opened, the system identifies the specific customer from the web address.
2. Data Retrieval: The system requests the full profile for that customer from the database.
3. Error Handling: If the customer cannot be found, the system displays a "not found" message. If any other technical issue occurs during the request, an error message is shown to the user.
4. Information Mapping: Once the data is successfully retrieved, the system automatically sorts the information into specific cards on the screen:

* Details Card: Displays contact information and the assigned salesperson.

* Group Card: Shows the customer’s assigned group.

* Tax Information Card: Displays tax and VAT identification numbers.

* Settings Card: Shows the current account status and credit terms.

* Prices Card: Displays the specific price list assigned to the customer.

* Changes Card: Provides an audit trail, including when the record was created or updated, who performed those actions, and the original source of the data.

2.3 Key Concepts

- Read-Only View: The page is designed for viewing information; data cannot be edited directly from this screen.
- Audit Trail: A record of "who" and "when" regarding the creation and modification of the customer profile, ensuring transparency and accountability.
- Account Status: A high-level indicator of the customer's current standing within the system (e.g., active, inactive, or on hold).
- Credit Terms: The specific payment conditions or credit limits agreed upon for that franchisee.

2.4 Business Value

This feature centralizes critical customer data, reducing the time staff spend searching for information across different systems. By providing a clear, organized view of a franchisee's profile—including their tax status, credit terms, and assigned salesperson—the page enables faster, more informed decision-making for customer support and account management teams. The inclusion of audit history also ensures that staff can easily verify the origin and maintenance history of customer records.

3. Data

3.1 Overview

The Franchisee Customer Detail Page feature provides a comprehensive, read-only view of a specific customer’s profile within the Lumi ERP system. This page acts as a centralized hub, pulling together all relevant business information—such as contact details, tax status, credit terms, and pricing assignments—to give staff a complete snapshot of a franchisee customer.

3.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to a specific franchisee customer’s profile, the system identifies the unique customer ID from the page address.
2. Data Retrieval: The system requests the full customer record from the database using that unique ID.
3. Validation: The system checks if the customer exists. If the ID is invalid or the record is missing, the system displays a "Customer Not Found" message.
4. Data Organization: Once the record is retrieved, the system organizes the information into logical categories (such as identity, tax, settings, and pricing) to ensure the data is presented clearly on the screen.
5.

Display: The organized data is populated into the corresponding read-only cards on the page, allowing the user to review the customer's full profile.

3.3 Key Concepts

- Franchisee Customer: A specific type of business partner within the ERP that requires detailed tracking for sales, tax, and credit purposes.
- Read-Only View: A display mode where information is presented for review purposes only, ensuring data integrity by preventing accidental changes while viewing.
- Audit Trail: A collection of tracking information (such as who created or updated the record and when) that provides transparency into the history of the customer profile.
- Account Status: A setting that indicates the current standing of the customer, helping staff quickly identify if an account is active or restricted.

3.4 Business Value

This feature streamlines daily operations by eliminating the need to search through multiple screens or systems to find customer information. By consolidating contact details, financial settings, and pricing data into one view, staff can make faster, more informed decisions regarding customer service, credit management, and sales support. The inclusion of audit data also ensures that the team maintains clear accountability and visibility over how and when customer records are managed.

BUSINESS REQUIREMENTS DOCUMENT

Customers - New Retail Customer

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Retail Customer" feature provides a dedicated interface for staff to register new retail clients within the Lumi ERP system. This page streamlines data entry by grouping information into logical sections—such as user details, tax information, and address management—ensuring that all necessary information is captured accurately before the customer record is created.

1.2 Step-by-Step Flow

1. Access & Authentication: Upon opening the page, the system verifies that the user is logged in. If the session is invalid, the user is redirected to the login screen.
2. Initialization: The system automatically loads default settings and populates necessary dropdown menus specifically configured for retail customers.
3. Data Entry: The user fills out the customer's profile, including personal details, tax information, and reporting settings.
4. Address Management: The user can add one or more addresses via a dedicated pop-up window. These addresses are held in a temporary list on the screen and are not saved to the database until the final submission.
5. Validation & Submission: When the user clicks "Save," the system validates that all required fields are present and ensures at least one address is designated as the "Main Address."
6. Completion: Once validated, the system sends the complete customer profile to the database. Upon a successful save, the user is automatically navigated to the new customer's profile page.

1.3 Key Concepts

- Retail Customer Type: A specific classification for customers that ensures the system applies the correct business rules and default settings during registration.
- Temporary Address List: A feature that allows users to compile multiple addresses (e.g., billing, shipping, or home) in a list before finalizing the customer record.
- Main Address: A mandatory designation for at least one address in the list, which the system uses as the primary contact point for the customer.
- Form Validation: An automated check performed by the system to ensure that critical information (such as names, emails, and required phone numbers) is provided before the record can be created.

1.4 Business Value

- Data Integrity: By enforcing validation rules and requiring a "Main Address," the system prevents incomplete or unusable customer records from entering the database.
- Operational Efficiency: The intuitive, tabbed, or card-based layout allows staff to quickly navigate and input complex customer data without feeling overwhelmed.
- Seamless Workflow: By handling the creation of the customer and their associated addresses in a single action, the system reduces the time spent on manual data entry and minimizes the risk of synchronization errors.

2. Logic

2.1 Overview

The "New Retail Customer" feature allows users to efficiently add a new retail-type customer to the Lumi ERP system. The process is designed to be seamless, allowing users to input customer contact details and multiple associated addresses in a single session. The system automatically categorizes these entries as "retail," ensuring consistency across the database.

2.2 Step-by-Step Flow

1. Access and Validation: When the page loads, the system verifies that the user is logged in. If the session is valid, it retrieves the necessary default settings and dropdown options to prepare the empty form.
2. Data Entry: The user fills out the customer’s name and email. Using the "Addresses Card," the user can add one or more addresses, specifying details like phone numbers, fax, and whether the address serves as the main or shipping location.
3. Submission: Once the user clicks the "Save" button, the system bundles the customer information and all listed addresses into a single request.
4. Processing: The system automatically tags the entry as a "retail" customer and sends the data to the database.
5. Outcome:

* Success: If the data is valid, the system creates the customer record and automatically redirects the user to the new customer's profile page.

* Failure: If an error occurs, the system keeps the user on the current page and preserves all entered information, allowing the user to correct mistakes and try again without losing their work.

2.3 Key Concepts

–

Retail Classification: A background setting that automatically labels the new entry as a "retail" customer, removing the need for the user to manually select a customer type.

- Addresses Card: A dedicated section of the form that manages a list of addresses, allowing for multiple locations to be attached to a single customer record before saving.
- State Preservation: A safety feature that ensures form data is not cleared if a submission fails, preventing data loss and reducing user frustration.
- Session Security: An automated check that ensures only authorized users can access the customer creation form, redirecting unauthorized users to the login screen.

2.4 Business Value

This feature streamlines the onboarding of new retail clients by centralizing data entry. By allowing users to define multiple addresses (such as billing or shipping) during the initial creation process, the system reduces the need for follow-up edits. Furthermore, the "state preservation" logic improves user productivity by ensuring that minor input errors do not result in the loss of time-consuming data entry.

3. Data

3.1 Overview

The "New Retail Customer" feature allows staff to efficiently add individual retail customers to the Lumi ERP system. This process captures essential contact information and multiple address details (such as billing or shipping locations) in a single, streamlined action. The system ensures data integrity by processing the customer profile and their associated addresses together as one complete unit.

3.2 Step-by-Step Flow

1. Initialization: When the page loads, the system retrieves necessary configuration data, such as available address types (e.g., billing, shipping, home), to populate the form fields.
2. Data Entry: The user fills out the customer’s profile and adds one or more addresses using the "Addresses Card" interface.
3. Submission: Upon clicking the "Save" button, the system validates the information provided to ensure it meets all requirements.
4. Processing: The system creates a new customer record marked as "retail" and simultaneously links all provided address details to that specific customer.
5.

Confirmation: Once the data is successfully saved, the system confirms the creation and navigates the user to the new customer's profile page. If an error occurs, the system retains the entered information so the user can make corrections without losing their work.

3.3 Key Concepts

- Retail Customer: A specific classification of customer within the ERP, automatically applied to all entries made through this feature.
- Address Card: A flexible section of the form that allows users to associate multiple locations with a single customer, including specific contact numbers and fax details for each location.
- Transaction: A safety mechanism that ensures the customer profile and their addresses are saved together; if one part fails, the entire process is rolled back to prevent incomplete or "orphaned" data.
- Validation: An automated check performed before saving to ensure all required fields are correctly formatted, preventing errors from entering the database.

3.4 Business Value

This feature simplifies the onboarding of retail clients by providing a dedicated, intuitive interface that eliminates manual data entry errors. By grouping customer profiles with their associated contact and location details, the system maintains a clean and organized database. This structure ensures that downstream processes—such as shipping, billing, and customer support—have immediate access to accurate, comprehensive information, ultimately improving operational efficiency and customer service.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Retail Customers Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Retail Customer Detail Page provides a comprehensive, read-only view of a specific customer's profile within the Lumi ERP system. This page acts as a central hub for staff to review all relevant information about a retail customer, including their contact details, tax status, internal business settings, and audit history, without the risk of accidental changes.

1.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the page, the system identifies the specific customer using their unique ID from the web address.
2. Data Retrieval: The system automatically fetches the customer's full profile from the database.
3. Loading & Error Handling: While the data is being retrieved, a loading indicator is shown. If the customer cannot be found or if a system error occurs, the user is notified accordingly.
4. Displaying Information: Once the data is successfully loaded, the page populates several organized sections (cards) with the customer's information.
5. Navigation & Interaction: The user can use the navigation bar to move through the system or click the "Customers" button to return to the main list. A dedicated "Edit" button is available if the user needs to update the customer's information.

1.3 Key Concepts

- Read-Only View: A display mode where information is presented for reference purposes only, ensuring data integrity by preventing accidental edits.
- Customer Cards: The page is organized into logical groupings (such as Tax Information, SAP Reporting, and Addresses) to make it easy for users to find specific data points quickly.
- Audit Trail: The "Changes" section tracks who created or updated the customer record and when, providing accountability and history.
- System Integration: The page displays specific fields (like SAP reporting values and tax identifiers) that are essential for syncing customer data with the company's broader financial and reporting systems.

1.4 Business Value

This feature streamlines customer management by providing a "single source of truth" for retail customer data. By consolidating identity, tax, and internal business settings into one clear, accessible page, staff can quickly verify customer details during daily operations. This reduces the time spent searching for information across different

systems and ensures that all departments—from sales to finance—are viewing consistent, accurate customer records.

2. Logic

2.1 Overview

The Retail Customer Detail page is designed to provide a comprehensive, read-only view of a specific customer's profile within the Lumi ERP system. When a user navigates to this page, the system automatically retrieves all relevant data associated with that customer and organizes it into logical sections for easy review.

2.2 Step-by-Step Flow

1. Page Initialization: When you open the Retail Customer Detail page, the system identifies the specific customer by their unique ID.
2. Data Retrieval: The system automatically requests the full customer profile from the database.
3. Data Processing: Once the information is received, the system maps the raw data into specific categories (such as contact details, tax information, and SAP reporting data).
4. Display: The information is populated into the corresponding cards on the screen.
5. Error Handling: If the customer cannot be found, the system displays a "not found" message. If any other technical issue occurs during retrieval, a general error message is shown to the user.

2.3 Key Concepts

- Read-Only View: The information displayed is for reference purposes only and cannot be edited directly on this page.
- Data Cards: The page organizes information into thematic groups (e.g., Tax Information, SAP Reporting, and Address details) to ensure the interface remains clean and easy to navigate.
- Audit Trail: The "Changes Card" provides transparency by showing when the record was created or last updated and by whom.
- Address Management: The system supports multiple address entries for a single customer, clearly labeling which is the primary address and which is used for shipping.

2.4 Business Value

This feature centralizes all critical customer data into a single, reliable source of truth. By providing a structured, read-only view, it allows sales and administrative staff to quickly verify customer details—such as tax IDs, SAP configurations, and contact information—without the risk of accidental data modification. This improves operational

efficiency and ensures that team members have accurate information when managing customer relationships or reporting.

3. Data

3.1 Overview

The Retail Customer Detail Page is a read-only view designed to provide a comprehensive snapshot of a specific customer's profile within the Lumi ERP system. When a user selects a customer, the system retrieves all relevant data—including contact details, tax information, SAP reporting codes, and address history—and displays it in an organized, easy-to-read format.

3.2 Step-by-Step Flow

1. Page Initialization: When a user opens the Retail Customer Detail Page, the system identifies the specific customer using their unique ID.
2. Data Retrieval: The system requests the full customer profile from the database, which includes the primary customer record and all associated address records.
3. Validation: The system checks if the customer exists. If the customer is found, the data is processed for display; if not, the system triggers a "not found" error message.
4. Information Mapping: The retrieved data is organized into specific sections (cards) on the screen, such as contact details, tax information, and audit logs.
5. Display: The page renders all information as read-only, ensuring that the user can view the complete customer history and configuration without the risk of accidental modification.

3.3 Key Concepts

- Read-Only View: A display mode where information is presented for reference purposes only and cannot be edited directly on the page.
- Audit Information: Tracking details that show when a record was created or last updated, and which user performed those actions.
- SAP Reporting Fields: Specific financial and organizational codes used to integrate customer data with SAP systems for accounting and reporting purposes.
- Address Association: The ability to link multiple addresses (such as billing or shipping) to a single customer profile, clearly identifying the purpose of each address.

3.4 Business Value

This feature provides a "single source of truth" for retail customer information. By centralizing identity, tax, financial, and address data into one view, staff can quickly verify customer details, resolve inquiries, and ensure that financial reporting (via SAP) is accurate. The read-only nature of the page protects data integrity, ensuring that sensitive customer and tax configurations remain stable while being accessible to authorized personnel.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Wholesale Customer Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Wholesale Customer Detail Page provides a comprehensive, read-only view of a specific wholesale customer's profile within the Lumi ERP system. This page centralizes all relevant business information—ranging from contact details and tax status to credit settings and account mappings—allowing staff to quickly review customer data in one place.

1.2 Step-by-Step Flow

1. Page Initialization: When a user opens the page, the system automatically identifies the specific customer ID from the web address.
2. Data Retrieval: The system fetches the full customer profile from the database.
3. Loading & Error Handling: While the data is being retrieved, a loading indicator is shown. If the customer cannot be found or a connection error occurs, the system displays a clear error message.
4. Information Display: Once loaded, the customer's information is organized into several logical sections (cards) for easy reading:

* Details: Core identity, contact information, and salesperson details.

* Changes: Audit trail showing when the record was created or last updated.

* Tax Information: Essential tax identifiers (NPWP, NPPKP, NITKU).

* Settings: Financial configurations, including credit limits, payment terms, and accounting accounts.

* Data Mapping, Group, and Prices: Specific operational categories for the customer.

5. Navigation: Users can return to the main customer list or click an "Edit" button to transition to the modification page if updates are required.

1.3 Key Concepts

- Read-Only View: The page is designed for viewing information; data cannot be changed directly on this screen to ensure data integrity.
- Audit Trail: A dedicated section that tracks the history of the record, showing who created or updated the information and when.
- Financial Configuration: A set of specific settings (such as credit limits and payment terms) that define how the system handles transactions for that specific wholesale customer.
- Data Mapping: A section that links the customer to specific internal categories or sales representatives, ensuring the customer is correctly categorized within the ERP.

1.4 Business Value

This feature improves operational efficiency by providing a "single source of truth" for wholesale customer data. By consolidating complex information—such as tax status, credit limits, and account settings—into one organized view, staff can make informed decisions faster, reduce the time spent searching for scattered information, and ensure that customer records are accurately maintained and audited.

2. Logic

2.1 Overview

The Wholesale Customer Detail Page provides a comprehensive, read-only view of a specific customer's profile within the Lumi ERP system. This page acts as a centralized dashboard, pulling together all relevant business, financial, and administrative data associated with a wholesale customer so that staff can quickly reference account details, tax status, and credit settings.

2.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to a specific customer's detail page, the system identifies the unique customer ID from the web address.
2. Data Retrieval: The system automatically requests the full customer record from the database using that unique ID.
3. Validation:

* If the customer is found, the system proceeds to organize the data.

* If the customer does not exist, the system displays a "Not Found" notification.

* If a technical error occurs during the request, the system displays an appropriate error message.

4. Information Mapping: The retrieved data is sorted into logical categories (such as contact details, tax information, and account settings) and displayed in the corresponding sections on the screen.

2.3 Key Concepts

- Read-Only View: The page is designed for viewing information; data cannot be edited directly from this screen to ensure record integrity.
- Audit Trail: The "Changes" section tracks the history of the record, including when it was created or last updated and by whom.
- Financial Configuration: This includes critical business settings such as credit limits, payment terms, and specific accounting accounts (e.g., invoice or deposit accounts) used for financial reporting.
-

Tax Compliance: Dedicated fields for tax identification numbers (NPWP, NPPKP, NITKU) ensure that all regulatory information is easily accessible for billing and compliance purposes.

2.4 Business Value

This feature streamlines operations by eliminating the need to search through multiple screens or physical files to find customer information. By providing a single, organized view of a wholesale customer—ranging from their contact person and assigned salesperson to their specific credit limits and tax status—staff can make faster, more informed decisions regarding sales, credit approvals, and account management.

3. Data

3.1 Overview

The Wholesale Customer Detail Page is a centralized view designed to provide a comprehensive look at a specific customer's profile within the Lumi ERP system. This page aggregates all relevant information—ranging from basic contact details and tax documentation to financial settings and account history—into a single, easy-to-read interface. It is designed as a read-only reference tool to ensure staff can quickly verify customer data and account configurations.

3.2 Step-by-Step Flow

1. Request Initiation: When a user selects a specific customer from the system, the application sends a request to retrieve that customer's unique profile using their identification code.
2. Data Retrieval: The system searches the database for the matching customer record.
3. Validation:

* If the customer record is found, the system proceeds to gather all associated details.

* If the record does not exist, the system returns a "Customer not found" notification.

4. Information Display: The retrieved data is organized and presented across several logical sections on the page:

* Details: Core identity, contact information, and banking details.

* Settings: Account configurations, tax information, and credit limits.

* Data Mapping: Assigned salesperson information.

* Prices: The specific price list assigned to the customer.

* Changes: Audit logs showing when the record was created or last updated and by whom.

3.3 Key Concepts

- Read-Only View: A display-only format that allows users to view information without the risk of accidentally modifying sensitive customer data.
- Audit Trail: A record of "who and when" regarding the creation and updates of a customer profile, ensuring accountability and data transparency.
- Financial Configuration: Specific settings related to how a customer is billed, including credit limits, payment terms, and tax-related accounts.
- Customer Profile: The complete collection of data points associated with a single entity, including contact, tax, and operational settings.

3.4 Business Value

This feature streamlines operations by eliminating the need to navigate through multiple screens to find customer information. By providing a "single source of truth" for wholesale customer data, staff can:

* Improve Response Time: Quickly answer customer inquiries regarding their account status, credit limits, or assigned pricing.

* Enhance Accuracy: Ensure that sales and finance teams are looking at the same, up-to-date information, reducing errors in billing and order processing.

* Support Compliance: Easily access tax documentation (such as NPWP and NPPKP) and audit logs, which are essential for maintaining accurate financial records and regulatory compliance.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Add Wholesale Customer

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Wholesale Customer" feature provides a dedicated interface for staff to register new wholesale clients into the Lumi ERP system. This page ensures that all necessary business information—such as contact details, tax identification, and credit settings—is captured accurately and consistently. The system is designed to streamline data entry by automatically loading default settings and providing organized sections for managing complex customer information.

1.2 Step-by-Step Flow

1. Access & Authentication: When a user navigates to the page, the system verifies their login status. If the user is not logged in, they are automatically redirected to the login screen.
2. Initialization: Once authenticated, the system fetches default settings and dropdown options (such as customer groups, tax settings, and currency) to ensure the form is pre-filled with standard business values.
3. Data Entry: The user completes the customer profile across several organized sections:

* User Details: Basic identity and contact information.

* Tax Information: Required tax identification numbers.

* Customer Grouping: Categorizing the customer for reporting and pricing.

* Settings: Financial configurations like credit limits and payment terms.

* Addresses: Managing multiple shipping or billing locations via a dedicated pop-up window.

4. Validation & Saving: Upon clicking "Save," the system validates the entered information. If any required data is missing or incorrect, the system alerts the user.
5. Completion: Once successfully saved, the new customer is added to the system, and the user is returned to the main customer list.

1.3 Key Concepts

- Default Settings: Pre-configured values that appear automatically when creating a new customer, reducing manual typing and ensuring consistency.
- Wholesale Type: A specific customer classification that triggers the system to load relevant wholesale-specific fields and business rules.
- Validation: A background check performed by the system to ensure that all mandatory fields are filled correctly before the data is permanently saved.
-

Data Mapping: The process of linking the system's background data (like tax rates or account types) to the dropdown menus on the screen, ensuring the user always sees the most current options.

1.4 Business Value

- Operational Efficiency: By pre-filling default values and organizing fields into logical cards, the system reduces the time and effort required to onboard new wholesale partners.
- Data Accuracy: Centralized validation prevents incomplete or invalid customer records from entering the database, which is critical for accurate financial reporting and tax compliance.
- Scalability: The structured approach to managing addresses and financial settings allows the business to handle complex wholesale relationships without increasing administrative overhead.

2. Logic

2.1 Overview

The "Add Wholesale Customer" feature provides a dedicated page for users to register new wholesale clients within the Lumi ERP system. The page is designed to be smart and efficient, automatically pre-filling standard settings and dropdown options to save time. It includes robust error handling to ensure that if any information is missing or incorrect, the user can easily fix it without losing the data they have already entered.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies that the user is logged in. If the user is not authenticated, they are automatically redirected to the login screen.
2. Form Initialization: Once verified, the system fetches default settings and list options (such as currencies, tax rates, and sales groups) specifically tailored for wholesale customers to pre-populate the form.
3. Data Entry: The user fills out the customer’s details. If the customer has multiple locations, the user can use the "Add Address" button to open a pop-up window, add address details, and see them appear in a summary table.
4. Submission: When the user clicks "Save," the system bundles all the information—including the customer profile and the list of addresses—and sends it to the server.
5. Outcome:

* Success: If the data is valid, the system saves the new customer and redirects the user to the newly created customer's profile page.

* Error: If there is an issue (e.g., a missing required field), the system displays the specific errors while keeping all entered information on the screen so the user can make corrections and try again.

2.3 Key Concepts

- Pre-population: The system automatically fills in common fields and dropdown menus based on wholesale-specific defaults, reducing manual data entry.
- Form Persistence: If a submission fails due to an error, the system retains the user's input, preventing the frustration of having to re-type information.
- Address Management: A dedicated table allows users to manage multiple addresses for a single customer, which are saved as part of the overall customer record.
- Wholesale Categorization: The system automatically tags these entries as "wholesale" to ensure they are processed correctly within the ERP.

2.4 Business Value

This feature streamlines the onboarding process for new wholesale partners by automating repetitive data entry and providing a clear, guided interface. By ensuring that all necessary wholesale-specific settings are applied by default, the system reduces the likelihood of human error and ensures that customer data is consistent and ready for immediate use in sales and accounting workflows.

3. Data

3.1 Overview

The "Add Wholesale Customer" feature provides a dedicated interface for your team to onboard new wholesale partners into the Lumi ERP system. This feature ensures that all necessary business information—including contact details, tax identification, and physical addresses—is captured accurately and stored in a structured format, allowing for seamless management of wholesale accounts.

3.2 Step-by-Step Flow

1. Data Entry: The user fills out the wholesale customer form, providing the customer's name, email, tax identification number, and one or more physical addresses.
2. Submission: Upon clicking "Save," the system gathers all entered information and automatically categorizes the entry as a "wholesale" customer.
3. Processing: The system sends this information to the database to create the new customer record.
4. Confirmation:

- If the information is valid and successfully saved, the system automatically redirects the user to the new customer's profile page.
-

If an error occurs (such as a missing field or duplicate email), the system keeps the user on the form and retains all previously entered data, allowing the user to make corrections and try again without losing their work.

3.3 Key Concepts

- Wholesale Customer: A specific category of client within the ERP that requires additional documentation, such as tax identification, for business-to-business transactions.
- Customer Record: The central profile that stores essential contact and identification information for a business partner.
- Address Management: The ability to associate multiple physical locations with a single customer record, ensuring accurate shipping and billing.
- Form Persistence: A safety feature that ensures data is not cleared if a submission fails, preventing the need for the user to re-type information.

3.4 Business Value

- Operational Efficiency: By standardizing the intake process for wholesale customers, the team can onboard new partners faster and with fewer errors.
- Data Integrity: Categorizing customers as "wholesale" and requiring specific fields like tax IDs ensures that your financial and shipping data remains clean and compliant.
- Improved User Experience: The error-handling logic reduces frustration by allowing users to fix mistakes quickly without having to restart the data entry process.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Franchisee Customer - Retail Customers Tab

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Retail Customers" tab is a dedicated view within the Franchisee Customer Details page. Its purpose is to provide a clear, organized list of all retail customers associated with a specific franchisee, allowing users to quickly reference key contact and identification information for those customers.

1.2 Step-by-Step Flow

1. Navigation Context: When viewing a franchisee's profile, the system highlights the "Customers" section in both the main and sub-menus to ensure the user knows their current location.
2. Page Identification: The page displays the specific name of the franchisee at the top, confirming which profile is currently being viewed.
3. Tab Selection: Within the franchisee details, the user selects the "Retail Customers" tab from the navigation bar.
4. Data Retrieval: The system automatically fetches the list of retail customers linked to that specific franchisee. A loading indicator is shown while this data is being retrieved.
5. Data Display: Once loaded, the information is presented in a table format containing the following details for each customer:

* A sequential row number.
* The unique customer code.
* The customer's full name.
* The customer's phone number.

1.3 Key Concepts

- Franchisee: A business partner or entity that manages a specific set of retail customers within the Lumi ERP system.
- Retail Customer: An individual or entity that purchases goods or services from a franchisee.
- Loading State: A temporary visual indicator that informs the user that the system is currently fetching data from the database.
- Navigation Tabs: A set of links that allow users to switch between different categories of information (such as general details, financial data, or retail customers) without leaving the franchisee's profile page.

1.4 Business Value

This feature improves operational efficiency by centralizing customer data. By providing a clean, readable list of retail customers directly within the franchisee's profile, staff can quickly verify customer identities and

contact information without needing to navigate to separate, disconnected reports. This ensures that franchisee management is streamlined and data-driven.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Retail Customer Edit Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Edit Retail Customer" page allows users to update existing customer information within the Lumi ERP system. When a user opens this page, it automatically loads the current details of the selected customer into a form. Users can modify various aspects of the customer profile—including personal details, tax information, SAP reporting data, customer groups, and address lists—before saving their changes.

1.2 Step-by-Step Flow

1. Data Loading: Upon opening the page, the system fetches the existing customer record and populates all form fields with the current data.
2. Editing: The user updates information across several sections (Details, Tax, SAP Reporting, Customer Groups, and Addresses).
3. Validation: As the user makes changes, the system performs real-time checks. Specifically, it ensures that the Name, Phone number (minimum 6 characters), Store, and Service Tax fields are correctly filled.
4. Submission: When the user clicks "Save," the system performs a final validation. If any required information is missing or incorrect, the system highlights the specific fields that need attention.
5. Completion: If the data is valid, the system saves the updates to the database. Upon a successful save, the user is redirected back to the customer list with a confirmation message.
6. Cancellation: If the user chooses to cancel at any point, all unsaved changes are discarded, and the user is returned to the customer list without any data being updated.

1.3 Key Concepts

- Form Validation: A built-in safety check that prevents the submission of incomplete or incorrect data, specifically requiring fields like Name, Phone, Store, and Service Tax.
- Data Persistence: The process of updating the customer record in the system database only when the "Save" button is clicked.
- Address Management: A flexible feature allowing users to add, edit, or remove multiple addresses for a single customer, with the ability to designate one as the "Main Address."
- Error Handling: If a save attempt fails due to invalid data, the system keeps the user on the page and highlights the specific errors so they can be corrected without losing the work already entered.

1.4 Business Value

This feature ensures data accuracy and operational efficiency by providing a centralized, user-friendly interface for maintaining customer records. By enforcing mandatory fields and providing immediate feedback on errors, the system prevents incomplete data from entering the ERP, which is critical for accurate reporting, tax compliance, and effective communication with retail customers.

2. Logic

2.1 Overview

The Retail Customer Edit page allows users to update existing customer information within the Lumi ERP system. When a user opens the page, the system automatically retrieves the customer's current details and populates the form. Users can modify various fields—including contact information, tax details, and addresses—and save their changes. The system includes built-in validation to ensure that essential information is provided before any updates are finalized.

2.2 Step-by-Step Flow

1. Page Initialization: When the page loads, the system fetches the specific customer's data and the necessary dropdown options (such as store locations and tax categories) simultaneously.
2. Data Loading: Once both the customer data and dropdown options are retrieved, the form is populated with the existing information. If the customer cannot be found, the user is automatically redirected back to the customer list.
3. User Editing: The user updates the desired fields. The system supports a wide range of data, including personal details, tax identifiers, SAP reporting codes, and address management.
4. Validation: When the user clicks "Save," the system checks that the Name, Phone (minimum 6 characters), Store, and Service Tax fields are filled.
5. Submission: If the data is valid, the system sends the updated information to the server.
6. Completion:

* If successful, the user is redirected to the Customer Detail page with a confirmation message.

* If there are errors (e.g., invalid data), the user remains on the edit page, and the specific fields with issues are highlighted so they can be corrected.

2.3 Key Concepts

– Data Mapping: The process of ensuring that information entered into the form fields (like "Name" or "Store") is correctly translated into the format the system database requires.

–

Validation Rules: Mandatory checks performed by the system to prevent incomplete or incorrect data from being saved.

- Dropdown Lookups: Pre-defined lists (like available stores or tax types) that ensure users select valid options rather than typing them manually.
- Address Management: The ability to add, edit, or remove multiple addresses for a single customer, including designating a "Main Address."

2.4 Business Value

This feature ensures data integrity and operational efficiency by providing a structured, validated interface for maintaining customer records. By enforcing mandatory fields and providing clear error feedback, the system reduces the risk of incomplete customer profiles, which is critical for accurate reporting, tax compliance, and effective customer management within the ERP.

3. Data

3.1 Overview

The Retail Customer Edit page allows staff to view and update information for existing retail customers within the Lumi ERP system. This feature ensures that customer records remain accurate and up-to-date by providing a structured form with built-in validation to prevent incomplete or incorrect data entry.

3.2 Step-by-Step Flow

1. Page Loading: When you open the edit page for a specific customer, the system automatically retrieves the customer's current details and populates the form.
2. Dropdown Preparation: Simultaneously, the system fetches the latest lists for stores and service tax options to ensure you are selecting from current, valid choices.
3. Validation Check: When you click "Save," the system checks your entries to ensure the customer's name, store, and service tax are provided, and that the phone number is at least 6 characters long.
4. Error Handling: If any required information is missing or invalid, the system will highlight the specific fields that need attention so you can correct them.
5. Successful Update: Once the information is valid and saved, you are redirected to the customer's detail page, where a confirmation message will appear to let you know the update was successful.
6. Missing Record Handling: If you attempt to access a customer record that no longer exists, the system will automatically redirect you back to the main customer list.

3.3 Key Concepts

- Data Validation: A safety check that ensures all required fields are filled out correctly before the system accepts the changes.
- Metadata: The supporting information (such as store names and tax categories) used to populate dropdown menus, ensuring consistency across the system.
- Retail Customer: A specific category of customer within the ERP that requires unique fields, such as store assignment and specific tax classifications.

3.4 Business Value

This feature streamlines the administrative process of managing retail customer data. By enforcing data quality at the point of entry, it reduces the risk of human error and ensures that reporting and tax calculations remain accurate. The intuitive validation and clear feedback loops help staff manage customer records efficiently, saving time and maintaining a reliable database.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Wholesale Customer Edit Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Wholesale Customer Edit page allows users to update existing customer information within the Lumi ERP system. This page provides a centralized interface to modify customer profiles, contact details, tax identification numbers, financial settings, and accounting preferences. Additionally, it includes a dedicated management section for handling multiple customer addresses.

1.2 Step-by-Step Flow

1. Accessing the Page: The user navigates to the Wholesale Customer Edit page, where all existing customer data is automatically loaded and displayed in the relevant fields.
2. Updating General Information: The user can modify primary details such as the customer's name, contact information, bank details, and tax IDs (NPWP, NPPKP, NITKU).
3. Managing Addresses:

* To update an existing address, the user clicks the "Edit" icon in the address table to open the Address Modal.

* To add a new location, the user clicks the "Add Address" button.

* Within the Address Modal, the user selects location details (Country, Province, District, etc.) and enters contact numbers. The system validates phone numbers in real-time to ensure they only contain allowed characters.
* The user saves or cancels the address changes to return to the main edit page.

4. Configuring Financials & Accounting: The user can update credit terms, limits, currency, and specific accounting accounts (such as invoice or deposit accounts).
5. Finalizing Changes: Once all updates are complete, the user clicks "Save" to commit the changes to the system or "Cancel" to discard all modifications.

1.3 Key Concepts

- Address Modal: A pop-up window used to manage specific location data, ensuring that address entry is structured and validated.
- Real-time Validation: A safety feature that checks phone number formats as the user types, preventing invalid data from being saved.
- Defaulting Logic: For certain financial and accounting fields, if the user leaves them blank, the system automatically applies pre-configured default settings (e.g., standard tax rates or default accounts).
- Data Mapping: The section of the page that links specific customer records to internal entities, such as the assigned Salesperson.

1.4 Business Value

-

Data Accuracy: By providing structured fields and real-time validation for contact information, the system reduces human error and ensures high-quality customer data.

- Operational Efficiency: The ability to manage multiple addresses and financial settings in one place streamlines the workflow for wholesale account managers.
- Flexibility: The system supports specific business requirements by allowing overrides for tax and accounting settings while providing sensible defaults to save time during data entry.

Customer - Customer Address Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Address Detail Page provides a centralized view of all physical addresses associated with a specific customer. This page is designed to help staff quickly verify contact information, shipping details, and geographic locations for Retail, Wholesale, and Franchisee customers. It ensures that address data is presented clearly and allows for easy navigation to edit information when necessary.

1.2 Step-by-Step Flow

1. Page Loading: When you navigate to the page, the system automatically retrieves the customer's profile and their complete list of registered addresses.
2. Navigation Context: The page displays the main navigation menu with the "Customers" tab highlighted, and a specific sub-menu tailored to the customer's business type (Retail vs. Wholesale/Franchisee).
3. Customer Identification: The customer’s name is displayed prominently at the top of the page for easy identification.
4. Address Display: All addresses associated with the customer are listed in individual cards. Each card includes:

* The full address (street, village, district, city, province, country, and postal code).
* Contact details (phone numbers and fax).
* Status flags (identifying if it is the main address or a shipping address).
* Geographic coordinates (latitude and longitude).
* Audit timestamps (when the address was created and last updated).

5. Editing: Each address card includes an "Edit" button that directs you to the customer's edit page to make any necessary updates.

1.3 Key Concepts

- Customer Type: A classification that determines which navigation menu options are shown, ensuring the interface is relevant to the specific business relationship (Retail, Wholesale, or Franchisee).
- Address Card: A structured summary block for a single address, containing all relevant contact, location, and status information.
- Status Flags: Simple "Yes/No" indicators that clarify if an address is designated as the primary (Main) address or the designated Shipping address.
- Audit Timestamps: Read-only information showing when an address record was first created and when it was last modified, providing transparency on data freshness.

1.4 Business Value

- Improved Data Accuracy: By displaying all address components (including geographic coordinates and status flags) in one place, staff can easily verify and maintain high-quality customer records.
- Operational Efficiency: The tailored navigation menus and clear address cards reduce the time spent searching for specific contact details, allowing staff to handle customer inquiries or logistics tasks faster.
- Seamless Workflow: The direct link to the edit page ensures that when discrepancies are found, staff can immediately transition to updating the information without navigating through multiple menus.

2. Logic

2.1 Overview

The Customer Address Detail feature provides a comprehensive view of all registered addresses for a specific customer within the Lumi ERP system. Whether the customer is a retail, wholesale, or franchisee account, this page consolidates their location data, contact information, and geographic coordinates into a clear, easy-to-read format.

2.2 Step-by-Step Flow

1. Identify Customer: When you open a customer’s profile, the system identifies the specific customer ID to ensure the correct data is retrieved.
2. Retrieve Basic Information: The system fetches the customer's core profile details (such as name and customer type) to confirm the identity of the account being viewed.
3. Fetch Address Records: The system pulls all associated address records linked to that customer.
4. Format and Display: The system combines individual address components—such as street, village, district, city, province, country, and postal code—into a single, readable address string. It then maps all relevant contact details (phones, fax, and address type) and location markers (latitude/longitude) to the screen for the user to review.

2.3 Key Concepts

- Address Consolidation: The process of taking separate data fields (like village, district, and city) and merging them into one complete, comma-separated address line for better readability.
- Address Categorization: The system distinguishes between different types of addresses, specifically identifying which entries are designated as the "Main Address" or the "Shipping Address."
- Geographic Tagging: The inclusion of latitude and longitude data, which allows the system to support mapping or location-based services for each address.

- Audit Timestamps: Every address record includes "Created At" and "Updated At" information, providing transparency on when the address data was first added or last modified.

2.4 Business Value

- Improved Data Accuracy: By automatically formatting address components, the system ensures that location data is presented consistently, reducing confusion for staff.
- Operational Efficiency: Users can quickly distinguish between billing, shipping, and main office locations, which is critical for managing logistics and communication for retail, wholesale, and franchisee accounts.
- Enhanced Customer Insight: Having all contact methods (multiple phone lines and fax) and precise geographic coordinates in one place allows for better coordination of deliveries and field services.

3. Data

3.1 Overview

The Customer Address Detail page is designed to provide a comprehensive view of location-specific information for any customer within the Lumi ERP system. Whether the customer is a retail shopper, a wholesale partner, or a franchisee, this feature ensures that all contact and geographical details are easily accessible and clearly presented in one place.

3.2 Step-by-Step Flow

1. Page Initialization: When you navigate to a customer's profile, the system automatically triggers a request to retrieve the specific address records associated with that customer.
2. Data Retrieval: The system searches the database for the address linked to that unique customer ID. If no address is found, the system will notify the user that the information is unavailable.
3. Data Formatting: Once the raw data is retrieved, the system organizes it into a user-friendly format. This includes combining the street address with the village, district, city, province, country, and postal code into a single, readable address line.
4. Display: The final, formatted information—including contact numbers, address type, and geographical coordinates—is displayed on the screen for the user to review.

3.3 Key Concepts

- Address Detail: A complete record containing not just the street address, but also the full regional hierarchy (village, district, city, etc.) and contact methods like phone and fax numbers.
- Address Classification: Indicators that define the purpose of the address, specifically identifying if it is the "Main Address" or the "Shipping Address" for the customer.

- Geographical Coordinates: Latitude and longitude data included to support mapping or location-based services.
- Audit Timestamps: Information showing when the address record was first created and when it was last updated, ensuring data transparency.

3.4 Business Value

This feature streamlines operations by providing a centralized, accurate source of truth for customer locations. By automatically formatting complex address data into a clean, readable layout, it reduces manual data entry errors and helps staff quickly verify shipping and contact details. This is essential for maintaining efficient logistics and communication across all customer types, including retail, wholesale, and franchise accounts.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Products /customers/[customer_id]/products

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Customer Products" feature provides a dedicated view within the Lumi ERP system to manage and view products associated with a specific customer. This page allows users to see a detailed list of products, apply customer-specific pricing or naming overrides, and perform administrative tasks like searching, filtering, and exporting data.

1.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the customer products page, the system automatically loads the specific customer's details to display their name in the page banner.
2. Filtering: The user uses the "Search and Filter" bar to narrow down the product list. The system requires selections for Membership, Vehicle, and Source before the search can be executed.
3. Data Retrieval: Once the search criteria are met and the button is clicked, the system fetches the relevant product list from the database based on the selected filters.
4. Table Display: The product list is rendered in a table, showing key details such as the standard SKU, product name, customer-specific aliases (name and SKU), and the specific discount percentage applied to that customer.
5. Interaction: Users can interact with the table by clicking on a SKU to view full product details, or by using the toolbar to add new products or export the current list to an Excel file.
6. Management: For individual items in the list, users have the option to edit or delete specific product associations as needed.

1.3 Key Concepts

- Alias Name/SKU: Customer-specific overrides that replace the standard product name or SKU on official documents like invoices, ensuring the customer sees terminology they recognize.
- Customer Discount (%): A specialized pricing rule that applies only to the selected customer, overriding standard catalog pricing.
- Search Filter Bar: A validation-controlled tool that ensures all required criteria (Membership, Vehicle, Source) are selected before the system performs a data lookup.
- Row Selector: A checkbox feature that allows users to select one or more products to perform bulk actions, such as removing multiple items at once.

1.4 Business Value

This feature streamlines account management by providing a clear, centralized view of customer-specific product catalogs. By allowing for "Alias" names and SKUs, the system reduces confusion for the customer during the

invoicing process. Furthermore, the ability to apply unique discount percentages directly within this view ensures accurate pricing and simplifies the management of complex wholesale or franchisee agreements.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Customer Vehicle

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Customer Vehicle page provides a centralized view of all vehicles registered to a specific customer. This page allows users to quickly identify a customer's fleet, view key technical specifications for each vehicle, and perform management tasks such as adding new vehicles or updating existing records.

1.2 Step-by-Step Flow

1. Page Initialization: When the page loads, the system automatically identifies the customer from the current web address.
2. Data Retrieval: The system fetches the customer's name to display in the page header and retrieves the full list of vehicles associated with that customer.
3. Display: The vehicle information is presented in a table, showing details like the registration number, make, model, and year. For heavy equipment, additional engine-specific details are displayed.
4. Navigation & Actions:

* Users can click on a vehicle's registration number to open a detailed view of that specific vehicle in a new tab.

* Users can click the "New Vehicle" button to navigate to a form to add a vehicle to the customer's account.

* Users can click the "Edit" button next to any vehicle to update its information.

1.3 Key Concepts

- Customer Banner: A prominent header at the top of the page that displays the name of the customer whose vehicles are currently being viewed.
- Vehicle Table: A structured list containing all relevant vehicle data, including technical specifications and engine details.
- Registration Number Link: A clickable identifier for each vehicle that provides quick access to more in-depth vehicle information.
- Action Buttons: Dedicated controls that allow users to either create a new vehicle entry or modify existing vehicle data.

1.4 Business Value

This feature streamlines fleet management by providing a clear, organized view of customer assets. By consolidating vehicle information and providing direct links to add or edit records, the system reduces the time spent searching for data and minimizes manual errors during updates. This ensures that customer records remain accurate and up-to-date, supporting better service and operational efficiency.

2. Logic

2.1 Overview

The Customer Vehicle feature provides a dedicated view within the Lumi ERP system to display a comprehensive list of vehicles associated with a specific customer. This page allows staff to quickly review vehicle details—such as registration, make, model, and engine specifications—and provides direct access to view or edit individual vehicle records.

2.2 Step-by-Step Flow

1. Request Data: When a user opens a customer's profile, the system automatically requests the list of all vehicles linked to that specific customer.
2. Data Retrieval: The system fetches the raw vehicle information, including registration numbers, physical characteristics, and engine details.
3. Information Mapping: The system organizes this raw data into a structured table format, ensuring that each piece of information (like "Make" or "Engine Power") appears in its correct column.
4. Action Linking: The system assigns unique identifiers to each vehicle row, enabling the "View" and "Edit" buttons to navigate the user to the correct specific vehicle record.
5. Display: The final list is presented to the user, allowing them to scan the customer's fleet and perform necessary updates.

2.3 Key Concepts

- Vehicle List: A centralized table view showing all vehicles owned or managed by a selected customer.
- Data Mapping: The process of taking technical information from the database and translating it into clear, readable labels for the user interface.
- Row Actions: Interactive elements within the table that allow users to click on a specific vehicle to either view its full details or open an edit screen.
- Engine Specifications: Detailed technical attributes (brand, model, year, and power) included in the list to help staff identify the correct vehicle configuration.

2.4 Business Value

- Improved Efficiency: Staff can instantly access a customer's entire vehicle history without searching through multiple screens or physical files.

- Data Accuracy: By standardizing how vehicle information is displayed, the system reduces the risk of misinterpreting technical details like engine models or registration numbers.
- Streamlined Workflow: Direct links to "View" and "Edit" actions allow users to transition seamlessly from reviewing a list to performing administrative tasks, saving time during customer interactions.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Return List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Customer Return List" feature provides a dedicated view within the Customer Detail page that allows users to see a comprehensive history of returns associated with a specific customer. This feature ensures that staff can quickly access and review return documentation, status, and financial details for any customer profile.

1.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the Customer Detail page, the system automatically verifies their login status. If the user is not logged in, they are redirected to the login screen.
2. Data Loading: Once authenticated, the system checks if the "Returns" tab is currently selected. If it is, the system retrieves the list of all returns associated with that specific customer.
3. Displaying Information: The page renders a header identifying the customer, followed by a "Customer Purchase Returns" section.
4. Data Presentation: The returns are displayed in a clear table format, showing key details for each transaction, such as the document number, date, status, amount, store location, and the staff member who created the record.

1.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can view sensitive customer return data.
- Customer Return Record: A digital document representing a specific return transaction, containing financial and administrative details.
- Return Status: A label indicating the current state of a return (e.g., Draft, Completed, or Cancelled), helping users understand if a return is still in progress or finalized.
- Document Number: A unique identifier assigned to each return, used for easy reference and tracking.

1.4 Business Value

- Improved Efficiency: Staff can instantly view a customer's return history without needing to search through separate filing systems or reports.
- Enhanced Customer Service: By having immediate access to return statuses and details, support staff can provide faster, more accurate answers to customer inquiries regarding their returns.
- Operational Transparency: Standardizing the display of return information (such as store location and the employee who processed the return) ensures better accountability and easier auditing of return transactions.

2. Logic

2.1 Overview

The "Customer Return List" feature provides a dedicated view within the Customer Detail page that displays a history of all returns associated with a specific customer. This allows staff to quickly review past return activity, including transaction details, status, and the store location where the return was processed.

2.2 Step-by-Step Flow

1. Triggering the View: When a user navigates to the Customer Detail page or switches to the "Return" tab, the system automatically initiates the data loading process.
2. Data Retrieval: The system requests the list of returns specifically linked to that customer from the database.
3. Processing:

- If the data is found, the system organizes the raw information into a user-friendly format for the table.
- If the customer cannot be found, the system displays a "not found" notification.
- If a technical error occurs during the request, the system displays an error message to the user.

4. Display: Once the data is successfully retrieved and processed, it is populated into the "Customer Purchase Returns" table for the user to view.

2.3 Key Concepts

- Return Tab Load: The automated process that ensures the return list is refreshed whenever the user views that specific section of the customer profile.
- Data Mapping: The process of translating raw system information into clear, readable labels (such as Document Number, Status, and Amount) so they can be easily understood by staff.
- Error Handling: Built-in safeguards that inform the user if a customer record is missing or if there is a temporary issue preventing the list from loading.

2.4 Business Value

This feature improves operational efficiency by centralizing customer return history. Instead of searching through multiple systems or physical records, support staff and store managers can instantly access a customer's return behavior. This transparency helps in resolving customer inquiries faster, identifying return patterns, and maintaining accurate records of store-level transactions.

3. Data

3.1 Overview

The "Customer Return List" feature provides a dedicated view within the Customer Detail page that displays a history of all product returns associated with a specific customer. This allows staff to quickly review a customer's return activity, including the status, value, and origin of each return, directly within the customer's profile.

3.2 Step-by-Step Flow

1. Triggering the View: When a user navigates to the "Return" tab on a Customer Detail page, the system automatically initiates a request to retrieve that customer's return history.
2. Data Retrieval: The system identifies the specific customer and fetches their unique list of returns from the database.
3. Processing:

* If the data is found, the system organizes the information (such as document numbers, dates, and amounts) to be displayed in a table.

* If the customer cannot be found, the system triggers a "not found" notification.

* If a technical error occurs during the request, the system displays an error message to inform the user that the information could not be loaded.

4. Display: Once retrieved, the return details are presented in a clear, structured list for the user to review.

3.3 Key Concepts

- Return Tab: A specific section within the Customer Detail page designed to isolate and display return-related transactions.
- Document Number: A unique reference identifier assigned to each specific return transaction for easy tracking.
- Status: The current state of the return (e.g., pending, completed, or rejected), helping staff understand where the return is in the process.
- Store Name: The specific location or branch where the return was initiated.
- Created By: The name of the staff member or system process that recorded the return.

3.4 Business Value

This feature improves customer service efficiency by centralizing return data. Instead of searching through multiple systems or physical records, staff can instantly view a customer's return history, which helps in identifying patterns, verifying return eligibility, and providing faster, more informed support during customer interactions.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Purchased Retails List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Customer Purchases" page is a read-only interface within the Lumi ERP system that allows staff to view a complete history of retail purchases made by a specific customer. This page is integrated into the customer profile section, ensuring that sales data is easily accessible while navigating through customer details.

1.2 Step-by-Step Flow

1. Security Verification: When the page loads, the system automatically checks if the user is currently logged in. If the session is invalid or expired, the user is redirected to the login page.
2. Data Retrieval: Once authenticated, the system fetches the purchase history specifically for the selected customer using their unique identifier.
3. Loading State: While the system retrieves the data from the database, a "Loading..." indicator is displayed to the user.
4. Data Presentation: Once the data is retrieved, the system populates a table with the customer's purchase records, including details such as the document number, transaction status, total amount, store location, and the creator of the record.
5. Navigation: Users can continue to use the main navigation menus or switch between different customer detail tabs (such as profile or other history) without leaving the customer context.

1.3 Key Concepts

- Authentication Check: A security step that ensures only authorized users can view sensitive customer financial data.
- Read-Only Interface: A design approach where the user can view and analyze information but cannot modify or delete the purchase records directly from this screen.
- Customer Context: The system maintains the specific customer's identity throughout the page, ensuring that the displayed purchase list is always relevant to the individual being viewed.
- Data Mapping: The process of taking raw information from the system's database and organizing it into clear, labeled columns (Document Number, Status, Amount, Store, and Created By) for the user.

1.4 Business Value

This feature provides immediate visibility into a customer's purchasing behavior, which is essential for customer support, sales analysis, and account management. By centralizing this information within the customer profile, staff can quickly answer inquiries about past transactions, verify order statuses, and understand a customer's history without needing to search through separate sales reports or accounting logs.

2. Logic

2.1 Overview

The "Purchased Retails List" feature provides a clear, organized view of a specific customer's shopping history directly within their profile page. This feature ensures that staff can quickly review past transactions, including order status and financial details, to better assist customers and manage account history.

2.2 Step-by-Step Flow

1. Security Check: When the page loads, the system automatically verifies that you are currently logged in. If your session has expired or you are not authenticated, you will be redirected to the login screen.
2. Data Retrieval: Once authenticated, the system fetches the complete list of purchase records associated with the specific customer you are viewing.
3. Information Formatting: The system organizes the raw purchase data into a user-friendly table, ensuring that key details like document numbers, transaction status, and purchase amounts are clearly displayed.
4. Display: The final list is presented on the Customer Detail page, allowing for immediate review of the customer's retail activity.

2.3 Key Concepts

- Authentication: A security step that confirms the user has permission to view sensitive customer data before the page displays any information.
- Purchase Record: A digital summary of a customer's transaction, containing details such as the document ID, the current status of the order, the total amount spent, the store location, and the customer identifier.
- Data Mapping: The process of taking raw information from our database and translating it into readable labels (e.g., "Document Number," "Status," "Amount") so that the information is easy for staff to interpret at a glance.

2.4 Business Value

This feature improves operational efficiency by centralizing customer history. Instead of searching through multiple systems or physical files, staff can instantly access a customer's purchase behavior. This enables faster customer support, more accurate account management, and a better overall understanding of customer engagement with the business.

BUSINESS REQUIREMENTS DOCUMENT

Customer - Add Vehicle

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Vehicle" feature allows users to register a new vehicle to a specific customer profile within the Lumi ERP system. This feature provides a structured form to capture essential vehicle details—such as make, model, year, and service history—ensuring that all necessary information is accurately recorded and linked to the correct customer account.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves a list of available vehicle makes and models to populate the selection menus.
2. Data Entry: The user fills out the form with vehicle details. The system identifies the customer by reading the ID from the current web address.
3. Dynamic Selection: The user selects a "Vehicle Type" (Car, Motorcycle, or Heavy Equipment). If "Heavy Equipment" is selected, additional specialized fields appear to capture specific machinery data.
4. Validation: The system ensures that mandatory fields (such as Make, Model, Year, and Odometer) are completed before allowing the user to proceed.
5. Submission: Upon clicking "Save," the system sends the collected information to the database.
6. Completion: If the save is successful, the user is automatically redirected to the customer's vehicle list. If an error occurs, an alert notifies the user.

1.3 Key Concepts

- Vehicle Metadata: The background data (makes and models) that ensures users can only select valid, pre-defined options for their vehicle.
- Conditional Fields: Form sections that only appear based on the user's previous choices (e.g., showing extra fields only for "Heavy Equipment").
- Required vs. Optional Fields: A distinction between data that must be provided to create a record (like the Year or Odometer) and supplementary information that can be added later (like Notes or Color).
- Customer Association: The process of linking a vehicle to a specific customer using a hidden identifier, ensuring the vehicle is correctly filed under the right account.

1.4 Business Value

This feature streamlines the customer management process by centralizing vehicle data entry. By enforcing standardized inputs and mandatory fields, it reduces data entry errors and ensures that service teams have

consistent, reliable information for every vehicle. This ultimately improves operational efficiency and supports better maintenance tracking for the customer.

2. Logic

2.1 Overview

The "Add Vehicle" feature allows users to register a new vehicle to a specific customer profile within the Lumi ERP system. This feature provides a structured form to capture comprehensive vehicle details—ranging from basic identification like the VIN and registration number to maintenance-related information like service dates and engine specifications.

2.2 Step-by-Step Flow

1. Initialization: When the "Add Vehicle" page loads, the system automatically retrieves the latest list of vehicle makes and models to populate the selection menus, ensuring users can only choose from valid, pre-defined options.
2. Data Entry: The user fills out the form with the vehicle's details, including identification (VIN, registration), technical specifications (engine capacity, transmission), and maintenance history (last/next service dates).
3. Submission: Upon clicking the "Save" button, the system validates the information and sends it to the database to create the new record.
4. Confirmation & Navigation: If the save is successful, the system automatically redirects the user to the customer’s "Vehicles" tab to view the updated list. If an error occurs during submission, the system displays an alert message to inform the user.

2.3 Key Concepts

- Metadata: The background data (such as lists of makes and models) that ensures the form is accurate and easy to use.
- Validation: The process of checking that the information entered into the form meets the system's requirements before it is saved.
- Record Creation: The action of permanently adding the new vehicle details to the customer's profile in the ERP.
- Redirect: The automatic movement of the user to a different page (the customer's vehicle list) once a task is successfully completed.

2.4 Business Value

-

Data Accuracy: By using standardized dropdowns for vehicle makes and models, the system prevents manual entry errors and ensures consistent data across the platform.

- Operational Efficiency: Centralizing vehicle information—including service history and technical specs—allows staff to manage customer assets more effectively and reduces the time spent searching for vehicle details.
- Improved User Experience: The seamless transition from adding a vehicle back to the customer's profile ensures a smooth workflow, allowing users to immediately verify that the new record was created correctly.

3. Data

3.1 Overview

The "Add Vehicle" feature allows you to register a new vehicle within the Lumi ERP system and associate it directly with a specific customer. This functionality captures comprehensive details about the vehicle—ranging from basic identification like the registration number and VIN to maintenance-related information like service history—ensuring that all relevant data is stored in one centralized location for easy management.

3.2 Step-by-Step Flow

1. Customer Verification: The system first checks to ensure the customer you are assigning the vehicle to exists in our records. If the customer cannot be found, the process will not proceed.
2. Data Collection: The system gathers all provided vehicle details, including identification numbers (VIN, registration, engine number), physical characteristics (make, model, color, year), and operational status (odometer reading, service dates, and active status).
3. Record Creation: The system generates a unique digital identifier for the new vehicle record.
4. Data Storage: All collected information is securely saved into the system database, linking the vehicle to the selected customer.
5. Confirmation: Once saved, the system confirms the successful creation of the vehicle record.

3.3 Key Concepts

- Customer Association: Every vehicle must be linked to a valid customer profile to ensure accurate billing, service tracking, and ownership records.
- Unique Identification: The system requires specific identifiers, such as the registration number and VIN, to prevent duplicate entries and ensure each vehicle is uniquely tracked.
- Maintenance Tracking: The feature includes fields for service dates and odometer readings, which help the system keep track of the vehicle's health and upcoming maintenance needs.

- Active Status: A toggle that allows you to mark a vehicle as "active" or "inactive," helping you manage your fleet or customer assets effectively without deleting historical data.

3.4 Business Value

- Centralized Data Management: By keeping all vehicle information within the ERP, your team has a "single source of truth," reducing the need for manual spreadsheets or disconnected records.
- Improved Service Planning: Capturing "last service" and "next service" dates enables proactive customer communication, allowing you to reach out for maintenance appointments at the right time.
- Operational Accuracy: Validating customer IDs and requiring unique identifiers like VINs minimizes data entry errors and ensures that service history is always attributed to the correct vehicle and owner.
- Enhanced Customer Insights: Having a detailed history of a customer's vehicle fleet allows for better-informed sales and service recommendations.

Company JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Company JSON Schema feature establishes a standardized structure for managing company information within the Lumi ERP system. This ensures that all company-related data—such as contact details, tax configurations, product settings, and operational preferences—is stored and retrieved consistently. This module acts as the foundation for creating, updating, and viewing company profiles, ensuring that the system remains organized and reliable as the business grows.

1.2 Step-by-Step Flow

1. Data Entry/Update: When a user creates or updates a company profile, the system validates the information against a strict set of rules (the "Schema") to ensure all required fields (like company name, address, and tax information) are present and correctly formatted.
2. Storage: Once validated, the core company information is saved to the main company database. Specialized settings, such as document tracking or platform-wide configurations, are linked to this record to keep the database clean and efficient.
3. Retrieval: When viewing a company's details, the system pulls the core information and automatically gathers related data (such as tax rates, product types, and custom settings) from various linked tables to provide a complete, unified view.
4. Filtering: For lists of companies, the system applies intelligent date-range logic. If a user doesn't specify a date, the system defaults to a 31-day window, ensuring that search results are always relevant and manageable.

1.3 Key Concepts

- Schema: A blueprint that defines exactly what information is required for a company profile and how that information should be formatted (e.g., ensuring an email address looks like an email).
- Validation: The process of checking incoming data against the schema to prevent errors or incomplete records from entering the system.
- JSONB: A flexible storage format used for complex settings (like POS or warehouse configurations) that allows the system to store varied, evolving settings without needing to change the entire database structure.
- Foreign Key: A link between different data tables (e.g., linking a company to a specific tax rate or customer type) that ensures data consistency across the platform.
- Pagination: A method of breaking large lists of data into smaller, manageable pages to ensure the software remains fast and responsive.

1.4 Business Value

-

Data Integrity: By enforcing strict rules on what data can be saved, the system prevents "dirty data," reducing errors in reporting and daily operations.

- Operational Efficiency: Standardized settings for things like document tracking and product attributes mean that the system behaves predictably, allowing staff to work faster with fewer manual adjustments.
- Scalability: The modular design—separating core company info from complex settings—allows the business to add new features or settings in the future without disrupting existing data.
- Improved Reporting: Because company data is structured consistently, generating accurate reports for tax, sales, and inventory becomes significantly easier and more reliable.

BUSINESS REQUIREMENTS DOCUMENT

Warehouse Type JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Warehouse Type JSON Schema feature establishes a standardized way for the Lumi ERP system to define and retrieve warehouse information. By creating a formal "blueprint" for warehouse data, we ensure that the system consistently handles warehouse details—such as names, codes, and status—whether they are being stored in the database or displayed in a list for users.

1.2 Step-by-Step Flow

1. Definition: The system uses a predefined schema to define exactly what information constitutes a "Warehouse" (e.g., ID, name, address, and active status).
2. Filtering: When a user requests a list of warehouses, they can apply filters such as the warehouse's active status or a specific date range to narrow down the results.
3. Retrieval: The system queries the database based on these filters, ensuring it only pulls the necessary information.
4. Pagination: To keep performance fast, the system breaks large lists into smaller, manageable pages. It uses a "cursor" (a specific ID) to help the system jump to the next set of results efficiently.
5. Response: The system returns the requested list of warehouses along with helpful metadata, such as the total number of records and the total number of pages available.

1.3 Key Concepts

- JSON Schema: A standardized set of rules that acts as a blueprint, ensuring all warehouse data is formatted correctly and consistently across the application.
- Pagination: A method of splitting a large list of data into smaller chunks (pages) so the system doesn't have to load everything at once, which keeps the interface responsive.
- Cursor-based Pagination: A high-performance way to navigate through lists by using a specific record ID as a starting point for the next page, rather than relying on simple page numbers.
- Filtering: The ability to narrow down search results based on specific criteria, such as only showing "active" warehouses or those updated after a certain date.

1.4 Business Value

- Data Integrity: By enforcing a strict schema, we prevent errors caused by missing or incorrectly formatted warehouse information, ensuring reliable data for inventory management.
- Improved Performance: The use of efficient pagination ensures that the system remains fast and responsive, even as the number of warehouses in the ERP grows over time.
-

Consistency: Standardizing how warehouse data is requested and returned makes it easier for different parts of the software to communicate, reducing development time and potential bugs when adding new features.

BUSINESS REQUIREMENTS DOCUMENT

Payment Type JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a structured way for the system to retrieve and display a list of payment methods. It allows users to search, filter, and view payment types (such as credit cards or bank transfers) while ensuring the data is organized into manageable pages for better performance and readability.

1.2 Step-by-Step Flow

1. Receive Request: The system receives a request containing specific filters (such as active status, name, or refund settings) and pagination preferences (which page to show and how many items per page).
2. Filter Data: The system searches the payment database, applying the requested filters to narrow down the results to only the relevant payment types.
3. Count Results: The system calculates the total number of items that match the filters to determine how many pages of data exist.
4. Calculate Pagination: Based on the total count and the requested page size, the system determines the total number of pages available.
5. Return Data: The system sends back the requested list of payment types along with the pagination details (current page, total pages, and total item count) to be displayed on the screen.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, numbered pages so the user doesn't have to load everything at once.
- Filtering: The ability to narrow down the list of payment types based on specific criteria, such as whether they are currently active or if they support refunds.
- Metadata: Additional information provided with the data (like the total number of pages) that helps the user interface know how to display navigation controls.

1.4 Business Value

- Improved Performance: By loading data in smaller chunks (pagination), the application remains fast and responsive even as the number of payment methods grows.
- Enhanced Usability: Users can quickly find specific payment methods using the search and filter options, reducing the time spent navigating through long lists.
- Data Accuracy: By centralizing the logic for how payment types are retrieved, the system ensures that users always see consistent, up-to-date information regarding which payment methods are active and their specific capabilities (like refund support).

2. Data

2.1 Overview

This feature provides the underlying logic for the "Payment Types" list screen within the Lumi ERP. It allows users to view, search, and filter the various payment methods configured in the system. By organizing these methods—such as credit cards or digital payment services—the system ensures that financial transactions are processed with the correct provider fees and accounting rules applied.

2.2 Step-by-Step Flow

1. Define Search Criteria: The system receives your filter requests, such as the payment name, the type of payment, whether refunds are enabled, or if the payment method should bypass standard invoice receivable processes.
2. Calculate Page Position: The system determines which specific "slice" of data to show based on your current page number and how many items you want to see per page.
3. Retrieve Filtered Data: The system searches the database for all active payment methods that match your specific criteria and sorts them alphabetically by name.
4. Calculate Total Count: The system performs a secondary check to count the total number of matching records. This allows the interface to display accurate pagination (e.g., "Showing 1-10 of 50 results").
5. Return Results: The system sends the requested list of payment methods and the total count back to your screen for display.

2.3 Key Concepts

- Payment Type: A specific method of payment (e.g., Visa, PayPal, Bank Transfer) that includes details like provider fees and specific accounting behaviors.
- Pagination: A method of breaking a large list of data into smaller, manageable pages to ensure the screen loads quickly and remains easy to navigate.
- Filtering: The ability to narrow down the list of payment methods based on specific attributes, such as whether the method is currently active or if it supports refunds.
- Provider Fee Rate: A percentage or fixed cost associated with a specific payment service, used by the ERP to calculate transaction costs.

2.4 Business Value

This feature centralizes the management of payment methods, ensuring that the finance team has a clear, searchable view of all available options. By automating the application of provider fees and accounting rules (like

skipping invoice receivables), the system reduces manual data entry errors and ensures that financial reporting remains consistent and accurate across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Payment Type Mappings JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Payment Type Mappings feature provides a structured way for the Lumi ERP system to retrieve and display how different payment methods are configured across various store locations. This functionality allows users to query specific payment settings for a company and receive a clean, organized list of active mappings, including the human-readable names of stores and payment types.

1.2 Step-by-Step Flow

1. Request Submission: The system receives a request containing filters such as the company ID, specific store ID, payment type ID, and status (active/inactive). It also accepts pagination settings (limit and offset) to manage the amount of data returned.
2. Data Retrieval: The system queries the database to find all relevant payment mappings. It automatically links the internal mapping records with the actual names of the stores and payment types to ensure the output is easy to read.
3. Filtering: The system applies the requested filters to narrow down the results, ensuring only the relevant mappings are returned.
4. Metadata Calculation: The system calculates the total number of available records for the given company to assist with navigation and pagination.
5. Response Delivery: The system returns the final list of mappings along with metadata, which includes the total count of records and the current pagination settings.

1.3 Key Concepts

- Payment Type Mapping: A configuration that links a specific payment method to a store location within the ERP.
- Filtering: The ability to narrow down results by specific criteria, such as viewing only active mappings or mappings for a single store.
- Pagination: A method of breaking large lists of data into smaller, manageable chunks using "limit" (how many items to show) and "offset" (where to start in the list).
- Metadata: Supplemental information provided with the data, such as the total number of records found, which helps the user interface display information correctly.

1.4 Business Value

This feature ensures that administrators and system users have clear visibility into how payments are configured across their organization. By providing a standardized way to fetch this data, the system enables:

- Operational Transparency: Easily verify which payment methods are active at specific store locations.
- Efficient Data Management: The use of pagination and filtering allows users to quickly find specific configurations without being overwhelmed by large datasets.
- Consistency: By resolving internal IDs into human-readable names (e.g., showing "Downtown Store" instead of a code), the system ensures that reports and management screens are intuitive and easy to interpret.

2. Data

2.1 Overview

The Payment Type Mappings feature allows the Lumi ERP system to organize and track how different payment methods (such as credit cards, cash, or digital wallets) are assigned to specific store locations. This feature provides a structured way to view and filter these assignments, ensuring that the system correctly identifies which payment types are active and available at each store within a company.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view payment mappings, which includes the specific company ID and optional filters (such as a specific store, a specific payment type, or the active status of the mapping).
2. Data Retrieval: The system searches the database for all records that match the provided company and filter criteria.
3. Information Consolidation: As the system retrieves the records, it automatically links the internal ID codes to their human-readable names (e.g., linking a store ID to the actual store name and a payment type ID to the payment type name).
4. Result Delivery: The system returns a clean, organized list of mappings, sorted by the date they were created, ready to be displayed in the user interface.

2.3 Key Concepts

- Payment Type Mapping: A record that links a specific payment method to a specific store location.
- Filtering: The ability to narrow down the list of mappings by store, payment type, or whether the mapping is currently active.
- Display Names: The human-readable labels (like "Downtown Store" or "Visa") that replace complex internal ID codes to make the data easy for users to understand.

- Pagination: A method of returning results in smaller, manageable chunks (using limits and offsets) to ensure the system remains fast and responsive.

2.4 Business Value

This feature provides transparency and control over financial configurations across a business. By allowing users to easily view and filter payment mappings, the business can:

- Improve Accuracy: Quickly verify that the correct payment methods are enabled for the right store locations.
- Enhance Reporting: Ensure that financial data is correctly categorized by store and payment type.
- Streamline Operations: Reduce manual effort in managing store-level configurations, allowing administrators to quickly identify and update active payment methods as business needs change.

BUSINESS REQUIREMENTS DOCUMENT

Village JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a structured way to retrieve a list of villages within the Lumi ERP system. It allows users to search for specific villages and filter them by their parent administrative regions (District, Regency/Municipality, or Province). The system ensures that each village is returned with its full hierarchical context, making it easy to understand exactly where a village is located within the regional structure.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to list villages, which may include optional search criteria such as a village name or specific parent region IDs (Province, Regency, or District).
2. Data Retrieval: The system queries the central area database, specifically looking for entries categorized as "villages."
3. Hierarchical Mapping: As it retrieves the village data, the system automatically links each village to its parent District, Regency/Municipality, and Province to provide a complete location profile.
4. Filtering and Sorting: The system applies any requested filters to narrow down the results and sorts the final list alphabetically by village name.
5. Pagination: To ensure performance, the system returns the results in manageable chunks (pages), including the total count of available records to help with navigation.
6. Response Formatting: The final data is packaged into a standardized format, ensuring that the village details and its parent hierarchy are clearly presented for the user.

1.3 Key Concepts

- Hierarchical Data: The system understands the relationship between different administrative levels, ensuring that a village is always associated with its correct district, regency, and province.
- Filtering: The ability to narrow down a large list of villages by name or by selecting a specific parent region, which helps users find information faster.
- Pagination: A method of breaking large datasets into smaller, manageable pages to keep the application fast and responsive.
- Standardized Schema: A consistent "blueprint" for how village information is delivered, ensuring that different parts of the software can reliably read and display the data.

1.4 Business Value

This feature simplifies regional data management by providing a reliable, searchable, and organized view of village information. By automatically linking villages to their parent regions, it reduces manual data entry errors and en-

sures that reporting and administrative tasks—such as assigning resources or tracking regional performance—are based on accurate, hierarchical location data.

BUSINESS REQUIREMENTS DOCUMENT

Province JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a standardized way for the Lumi ERP system to retrieve a list of provinces. It allows users to search for specific provinces by name and view the results in manageable chunks (pagination), ensuring the system remains fast and easy to navigate even as the number of provinces grows.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a list of provinces, which may include a search term (to filter by name) and pagination settings (to specify how many results to show and where to start).
2. Data Retrieval: The system queries the central area database, specifically looking for entries categorized as "province."
3. Filtering and Sorting: The system applies the optional name filter to narrow down the results and automatically sorts the resulting list alphabetically by name.
4. Pagination Calculation: The system calculates the total number of provinces that match the search criteria, allowing the user to see how many pages of results are available.
5. Response Formatting: The system packages the requested subset of provinces (including their unique ID, code, and name) along with the pagination details and sends this information back to the user.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down a list of results by typing a specific name or keyword.
- Province Category: A specific classification within the area database that ensures only relevant geographic data is returned.
- Sorting: The automatic organization of data in alphabetical order to make it easier for users to find what they need.

1.4 Business Value

- Improved User Experience: By providing sorted and paginated lists, users can find the specific province they need quickly without scrolling through long, unorganized lists.
- System Efficiency: Pagination ensures that the application only loads a small amount of data at a time, which keeps the software responsive and reduces the load on the server.
- Data Consistency: By using a standardized schema for province data, the ERP ensures that information is presented uniformly across different parts of the system, reducing errors and simplifying future development.

BUSINESS REQUIREMENTS DOCUMENT

Regency JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Regency JSON Schema feature provides a standardized way for the system to retrieve and display a list of regencies. It ensures that when the application requests regency data, the information is organized consistently, including the regency's details and its associated province, while also supporting efficient navigation through large lists using pagination.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view a list of regencies. This request can optionally include a search term (to filter by name) or a specific province ID (to filter by region).
2. Data Retrieval: The system queries the central area database. It specifically looks for entries marked as "regency" and automatically links them to their parent "province" to provide full context.
3. Filtering and Sorting: The system applies the requested filters and sorts the resulting list alphabetically by the regency name.
4. Pagination: To keep the response manageable, the system limits the number of results returned at once and calculates the total number of available records.
5. Response Formatting: The final data is packaged into a structured format that includes the list of regencies (with their IDs, codes, names, and parent province information) alongside the pagination details.

1.3 Key Concepts

- Regency: A specific administrative area type within the system that belongs to a parent province.
- Pagination: A method of breaking a large list of data into smaller, manageable pages (using a limit and offset) to improve system performance and user experience.
- Filtering: The ability to narrow down the list of regencies by searching for a specific name or by selecting a parent province.
- JSON Schema: A standardized "blueprint" that defines exactly how the data should be structured, ensuring that different parts of the software can communicate and understand the information reliably.

1.4 Business Value

This feature ensures data consistency across the Lumi ERP platform. By standardizing how regency information is requested and delivered, we reduce the risk of errors in reporting and data entry. Furthermore, the built-in filtering and pagination capabilities allow users to quickly find the specific geographic information they need, even as the database grows, leading to a more responsive and user-friendly experience.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/service_products

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for external systems to retrieve a list of service products stored in the Lumi ERP. By default, the system will return only active service products, ensuring that users are working with current and relevant data. The feature is designed to be flexible, allowing users to search for specific items, filter by recent updates, or organize the results in a specific order.

1.2 Step-by-Step Flow

1. Request Initialization: The system receives a request to list service products. It automatically sets default values for pagination (starting on page 1 with up to 100 items) and ensures that only "active" products are included unless otherwise requested.
2. Filtering: The system applies any specific filters provided by the user, such as searching for a specific product ID, a unique SKU, or products that have been updated after a certain date.
3. Sorting: The system organizes the list based on the user's preferred field (such as ID or name) and direction (ascending or descending).
4. Pagination: The system limits the number of results returned per request (up to a maximum of 300) to ensure the response remains fast and manageable.
5. Data Delivery: The system retrieves the requested information—including the product ID, SKU, name, status, and creation/update timestamps—and sends it back to the user. If an error occurs during this process, the system provides a clear error message.

1.3 Key Concepts

- Pagination: A method of breaking a large list of items into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down the list of products based on specific criteria, such as status (active/inactive) or modification date.
- SKU (Stock Keeping Unit): A unique identifier used to track individual service products within the system.
- Sorting: The process of arranging the list in a specific order, such as alphabetical or chronological, to make it easier to find specific information.

1.4 Business Value

This feature enables seamless integration between the Lumi ERP and other business tools. By providing a standardized way to pull service product data, it ensures that external applications always have access to accurate,

up-to-date product information. The built-in filtering and pagination capabilities allow for efficient data retrieval, reducing the load on the system while providing the flexibility needed for various reporting and synchronization tasks.

2. Data

2.1 Overview

The Service Product API endpoint allows users to retrieve a list of service products currently stored in the Lumi ERP system. By default, the system provides a clean, organized list of all "active" products, but it also includes flexible search and organization tools to help users find specific items quickly.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to fetch service products.
2. Filtering: The system applies any requested filters (such as searching by a specific ID, SKU, or checking for updates since a certain date). If no specific "active" status is requested, the system automatically filters for active products only.
3. Sorting: The results are organized based on the user's preference (e.g., by name, date, or SKU) in either ascending or descending order.
4. Pagination: To ensure the system remains fast, the results are broken into manageable pages. The system calculates which specific "slice" of data to show based on the requested page number and limit.
5. Data Delivery: The system retrieves the final, filtered, and sorted list and delivers it to the user. If the requested item cannot be found or an error occurs, the system provides a clear status message (such as "Not Found" or "Bad Request").

2.3 Key Concepts

- Pagination: A method of breaking a large list of items into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to narrow down the list of products based on specific criteria, such as whether a product is active or when it was last updated.
- Sorting: The process of arranging the list in a specific order (e.g., alphabetical or chronological) to make it easier to navigate.
- SKU (Stock Keeping Unit): A unique identifier used to track specific service products within the system.
- Active Status: A toggle that determines whether a product is currently available for use; the system defaults to showing only active items to keep the workspace uncluttered.

2.4 Business Value

This feature provides a reliable and efficient way for users to access service product data. By offering built-in filtering and sorting, it reduces the time spent searching for information. Furthermore, the pagination feature ensures that the application remains responsive even as the number of service products grows, supporting the scalability of the Lumi ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/service_products?utf8= &q[attribute_predicate]=value&...&page_rows=

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Service Products API endpoint allows users to retrieve a filtered and organized list of service products from the Lumi ERP system. It provides a flexible way to search for specific items based on their attributes, such as name, SKU, type, or assigned tags. This feature is designed to help users quickly locate relevant service products while maintaining system performance through pagination and controlled access.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to view the service product list.
2. Validation: The system checks that all search criteria provided are formatted correctly. If the request is malformed or contains invalid values, the system rejects the request.
3. Reference Verification: If the user is filtering by a specific "Type" or "Tag," the system confirms that these categories actually exist in the database before proceeding.
4. Data Filtering: The system applies the requested filters (SKU, name, type, or tags) to narrow down the list of service products.
5. Sorting and Pagination: The system organizes the results based on the user's preferred sort order and limits the number of items returned to a manageable size.
6. Data Delivery: The system returns the final list of matching service products, including key details like the ID, SKU, name, type, and creation date.

1.3 Key Concepts

- Filtering: The ability to narrow down a large list of items by specific criteria, such as searching for a product by its name or SKU.
- Pagination: A method of breaking a large list of results into smaller, manageable pages to improve performance and readability.
- Sorting: The ability to arrange the results in a specific order (e.g., alphabetically by name).
- Authentication & Authorization: Security measures that ensure only verified users with the correct access rights can view the data.
- Validation: A process that ensures the data sent by the user meets the system's requirements, preventing errors or invalid searches.

1.4 Business Value

This feature empowers users to efficiently manage and locate service products within the Lumi ERP. By providing robust search and filter capabilities, it reduces the time spent manually browsing through records. Furthermore, by including pagination and strict permission checks, the API ensures that the system remains fast, secure, and reliable, even as the volume of service product data grows.

2. Data

2.1 Overview

This feature provides a search and filtering interface for the "Service Products" catalog within the Lumi ERP system. It allows users to retrieve a specific list of products by applying various criteria—such as searching by name or SKU, filtering by product type, or narrowing results down by specific tags. The system also supports sorting and pagination to ensure that large lists of products are easy to navigate and manage.

2.2 Step-by-Step Flow

1. Receive Request: The system receives a request containing search criteria, sorting preferences, and the number of items to display per page.
2. Apply Filters: The system processes the provided filters:

* Text Search: Matches partial text for SKU or product name.

* Type Filtering: Verifies that the requested product type exists in the system before applying the filter.

* Tag Filtering: Verifies that all requested tags exist before filtering the products to include only those associated with those specific tags.

3. Apply Sorting: If a sort preference is provided (e.g., sorting by name), the system organizes the results accordingly.
4. Apply Pagination: The system limits the number of results returned based on the requested page size.
5. Return Results: The system returns the filtered, sorted, and paginated list of service products to the user.

2.3 Key Concepts

– Filtering: The ability to narrow down a large list of items based on specific attributes like name, SKU, type, or tags.
– Validation: A safety check performed by the system to ensure that any categories or tags requested by the user actually exist in the database before attempting to filter by them.
– Sorting: The process of arranging the final list of results in a specific order (e.g., alphabetical).

- Pagination: A method of breaking a large dataset into smaller, manageable chunks (pages) to improve performance and readability.
- Partial Match: A search capability where the system finds results that contain the entered text, even if it is only a portion of the full name or SKU.

2.4 Business Value

This feature significantly improves the user experience for staff managing the service catalog. By providing robust search and filter capabilities, users can quickly locate specific service products without manually scanning through the entire database. This reduces administrative time, minimizes errors in product selection, and ensures that the ERP system remains an efficient tool for daily operations.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/service_products/inactive

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of all service products that have been deactivated within the Lumi ERP system. By accessing this list, users can view services that are no longer active, helping with record-keeping, auditing, or potential reactivation. The system also allows users to narrow down this list by applying specific filters, such as service type or category tags.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to view this information. If not, access is denied.
2. Filter Extraction: The system checks if the user has requested to filter the results by a specific service type or a specific tag.
3. Validation: If filters are provided, the system confirms that the requested type or tag actually exists in the database. If a requested filter does not exist, the system reports an error.
4. Data Retrieval: The system searches the database for all service products marked as "inactive." If filters were provided, it further narrows the search to only include items matching those specific criteria.
5. Display: The system returns the final list of inactive service products to the user.

1.3 Key Concepts

- Inactive Service Products: Items that have been "soft-deleted" or deactivated in the system, meaning they are hidden from standard views but still stored for historical reference.
- Filtering: The ability to refine the list of inactive items by selecting a specific "Type" or "Tag," making it easier to find relevant records.
- Validation: A safety check performed by the system to ensure that any filters requested by the user are valid and exist in the database before attempting to search.
- Unauthorized Access: A security measure that ensures only authenticated users can view sensitive service product data.

1.4 Business Value

This feature improves data management by providing a dedicated view for deactivated services. Instead of losing track of items that are no longer in use, administrators can easily audit or review these records. The addition of filtering capabilities ensures that users can quickly locate specific inactive services without having to manually sort through a large, unfiltered list, thereby saving time and improving operational efficiency.

2. Data

2.1 Overview

The "Inactive Service Products" feature provides a way to retrieve a list of service products that have been deactivated within the Lumi ERP system. This endpoint is designed to support the "Inactive" tab in the user interface, allowing users to view, manage, or potentially restore services that are no longer in active use.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to fetch inactive service products.
2. Validation: The system checks if any optional filters (such as specific service types or tags) are provided. If a filter is provided but does not exist in the system, the request is rejected with a "Not Found" error.
3. Data Retrieval: The system queries the database for all service products marked as "inactive."
4. Filtering: If filters were provided, the system narrows the list to only include items matching those specific criteria.
5. Pagination: The results are organized into pages (based on the requested page number and limit) to ensure the system remains performant even with a large number of inactive items.
6. Sorting: The results are returned in order of creation, with the most recently deactivated or created items appearing first.
7. Response: The system returns the requested page of data along with metadata (such as the total count of inactive items) to the user.

2.3 Key Concepts

- Inactive Status: A "soft-deleted" state for service products, meaning the data is hidden from active workflows but remains in the system for record-keeping or potential reactivation.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve loading speeds and user experience.
- Filtering: The ability to narrow down the list of inactive products by specific categories (Service Type) or labels (Service Tag).
- Metadata: Supplemental information returned with the list, such as the total number of inactive products, which helps the user interface display accurate page numbers and navigation.

2.4 Business Value

This feature improves data management by providing clear visibility into discontinued or deactivated services. By allowing users to filter and browse these items, the business can:

* Maintain Data Integrity: Keep a historical record of services without cluttering the active product catalog.

* Improve Operational Efficiency: Enable staff to quickly locate and potentially reactivate services that were previously retired.

* Enhance Reporting: Provide better insights into the lifecycle of service offerings by tracking what has been deactivated and why.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/service_products

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for the Lumi ERP system to create new service products. When a user saves a new service product in the application, this process handles the validation of the information, ensures the product is unique to the company, and saves the details—including pricing, tax settings, and categorization tags—into the system database.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the user is logged in and authorized to create new products.
2. Input Validation: The system checks that all mandatory information (such as the SKU, product name, tax details, and price) has been provided.
3. Business Rule Check: The system ensures that the SKU (Stock Keeping Unit) is unique for the specific company to prevent duplicate product entries.
4. Data Storage: If all checks pass, the system saves the new service product details into the database.
5. Tag Association: If any tags were selected for the product, the system links those tags to the new product record.
6. Confirmation: Once successfully saved, the system returns the details of the newly created product so the application can display it to the user.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track individual service products within a company.
- Validation: The process of ensuring that required fields are filled out correctly and that business rules (like unique identifiers) are followed before saving data.
- Persistence: The act of permanently saving the product information into the system's database.
- Tag Mapping: The process of linking specific labels or categories to a product, allowing for better organization and reporting.

1.4 Business Value

This feature ensures data integrity by preventing duplicate product entries and enforcing the collection of essential financial and operational data (like tax and pricing information). By automating the creation process, it allows users to quickly and reliably add services to the system, ensuring that all products are correctly categorized and ready for use in billing and reporting.

2. Data

2.1 Overview

This feature provides the functionality for the "Save" button on the Add Service Product page. It allows users to create a new service product in the Lumi ERP system by submitting a form containing details such as the product name, pricing, tax settings, and categorization tags. The system ensures that all necessary information is provided and that the product identifier (SKU) is unique to the company before saving the data.

2.2 Step-by-Step Flow

1. Validation: The system checks the incoming request to ensure all required fields (such as Name, Price, and Tax information) are present. It also verifies that the provided SKU is not already in use by another service product within the same company.
2. Data Persistence: If validation passes, the system creates a new record for the service product, storing all provided details like descriptions, pricing, and tax configurations.
3. Tag Association: If any tags were selected for the service product, the system creates individual links between the new product and those tags.
4. Confirmation: Once the data is successfully saved, the system returns the details of the newly created product, allowing the application to navigate the user to the product's detail page.

2.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier for a service product that must be distinct for every product within a single company.
- Validation: The process of checking that the data submitted is complete and follows business rules (e.g., preventing duplicate SKUs) before it is saved.
- Atomicity: A safety mechanism ensuring that the service product and its associated tags are saved together as a single unit; if any part of the process fails, the entire operation is canceled to prevent data errors.
- Tags: Labels used to categorize service products for easier organization and reporting.

2.4 Business Value

This feature streamlines the service management process by providing a reliable and standardized way to add new offerings to the ERP. By enforcing data integrity—such as unique SKU requirements and mandatory tax fields—the system prevents common data entry errors, ensures accurate financial reporting, and maintains a clean, organized catalog of services that the business provides.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/service_products/new

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides the necessary data to initialize the "Create New Service Product" page in the Lumi ERP system. When a user navigates to the page to add a new service, this process automatically gathers all the required dropdown options (such as service types, tax categories, and accounting codes) and sets the initial default values for the form fields. This ensures that the user starts with a pre-configured, ready-to-use form, reducing manual entry and ensuring consistency across the system.

1.2 Step-by-Step Flow

1. Data Retrieval: The system gathers all master data lists required for the form, including service types, tags, tax categories, accounting codes, and tax-related measurement units.
2. Default Configuration: The system identifies the company's default Chart of Accounts (COA) to ensure that financial fields are pre-filled with the correct accounting settings.
3. Form Preparation: The system bundles the default settings (such as "Active" status and starting price) with the master data lists.
4. Response Delivery: The prepared data is sent to the user's browser, populating the "Create Service Product" form with all necessary options and starting values.

1.3 Key Concepts

- Master Data: The standardized lists of information (like tax codes or service types) that ensure users select from approved, consistent options rather than typing them manually.
- Form Defaults: Pre-set values that appear automatically when a user opens a new form, designed to save time and minimize errors for common settings.
- Chart of Accounts (COA): The financial framework used to categorize transactions; the system automatically selects the default account to ensure financial data is routed correctly.
- Dropdown/Multi-select Options: The lists of choices provided to the user to ensure that data entered into the system remains organized and searchable.

1.4 Business Value

- Efficiency: By pre-loading defaults and dropdown options, users can create new service products much faster without needing to look up or manually input standard settings.
- Data Accuracy: Using pre-defined lists for taxes, accounting codes, and service types prevents typos and ensures that all service products are categorized correctly for financial reporting.
-

User Experience: The system provides a seamless "Add" experience by ensuring the form is fully prepared the moment the user opens it, eliminating the need for secondary lookups or manual configuration.

2. Data

2.1 Overview

The "New Service Product" API endpoint is designed to prepare the user interface for creating a new service in the Lumi ERP system. When a user navigates to the "Add Service Product" page, this feature automatically gathers all the necessary background data—such as tax categories, account codes, and service types—and pre-fills the form with standard default settings. This ensures that the user has a consistent, ready-to-use form immediately upon arrival.

2.2 Step-by-Step Flow

1. Data Retrieval: The system simultaneously collects all required reference information from the database, including service types, tags, tax rules, accounting codes, and measurement units.
2. Default Configuration: The system generates a "blank" template for the new service. This includes setting standard values for fields like "Active" (set to true), "Price" (set to 0), and pre-selecting specific default accounting codes for tax purposes.
3. Form Delivery: The system combines the pre-filled default values and the full list of available options (for dropdown menus) into a single package and sends it to the user's screen.
4. Error Handling: If the system fails to retrieve the necessary data or if the user is not authorized, the system will return an appropriate error message to ensure the application remains stable.

2.3 Key Concepts

- Reference Data: The background lists (such as tax types or service categories) that populate dropdown menus, ensuring users select from standardized, pre-approved options.
- Form Defaults: Pre-set values that appear automatically when a user opens a new form, reducing manual data entry and ensuring consistency across the system.
- Chart of Accounts (COA): A structured list of financial accounts used to categorize transactions; the system automatically selects the correct default accounts for tax-related entries.
- JSON Schema: The standardized "blueprint" or format that ensures the data sent from the server is organized exactly how the user interface expects it to be.

2.4 Business Value

-

Improved Efficiency: By pre-loading dropdowns and default settings, users spend less time manually configuring standard fields, allowing them to create new service products faster.

- Data Accuracy: Pre-selecting default accounting codes and tax settings reduces the risk of human error, ensuring that financial data is categorized correctly from the moment a service is created.
- User Experience: The feature provides a seamless, responsive experience by ensuring the "Add" page is fully populated and ready for input the moment the user opens it.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/service_products/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve detailed information about a specific service product. By using a unique identifier, the system can instantly pull up the relevant data—such as the name, description, price, and status—to display on the Service Product Detail page.

1.2 Step-by-Step Flow

1. Security Check: The system first verifies that the person requesting the information is authorized to access the ERP data. If they are not logged in or lack permission, the request is denied.
2. Identify the Product: The system looks at the specific ID provided in the request to determine exactly which service product is being searched for.
3. Database Search: The system searches the product records to find a match for that specific ID.
4. Return Information:

* If the product is found, the system displays all relevant details (name, price, description, etc.).

* If the ID does not exist, the system informs the user that the product could not be found.

* If an unexpected technical issue occurs, the system provides an error message.

1.3 Key Concepts

- Service Product: A specific offering or service managed within the ERP system that has its own unique price, description, and status.
- Unique Identifier (ID): A specific code or number assigned to each service product, ensuring the system retrieves the correct item every time.
- Authentication: A security gate that ensures only verified users can view sensitive business data.
- Status (is_active): A flag indicating whether the service product is currently available for use or has been deactivated.

1.4 Business Value

This feature ensures that users can quickly and accurately view the details of any service product without manual searching. By providing a reliable, secure way to fetch this data, it supports consistent information display across the platform, reduces the risk of errors when viewing product details, and ensures that only authorized personnel can access sensitive service information.

2. Data

2.1 Overview

This feature provides a way for the Lumi ERP system to retrieve specific details about a single service product. By using a unique identifier, the system can instantly pull up information such as the product name, description, pricing, and current status. This functionality is designed to power the "Service Product Detail" page, ensuring that users always see accurate and up-to-date information for the item they are viewing.

2.2 Step-by-Step Flow

1. Request: The system receives a request to view a specific service product using its unique ID.
2. Search: The system searches the database to find the record that matches that specific ID.
3. Validation:

* If the record is found, the system proceeds to prepare the data.

* If no record is found, the system returns a "Not Found" notification.

4. Formatting: The system organizes the raw database information into a clean, standardized format, including the product's name, price, currency, active status, and timestamps for when it was created or last updated.
5. Delivery: The formatted details are sent back to the user interface to be displayed on the screen.

2.3 Key Concepts

- Unique Identifier (ID): A specific code assigned to each service product that acts as a digital fingerprint, ensuring the system retrieves the correct item.
- Service Product Detail: The complete set of information regarding a service, including its cost and availability, presented in a structured way.
- Standardized Format: A consistent layout for data that ensures different parts of the software can easily understand and display the information.
- Metadata: Background information about the record, specifically the dates when the product was first created and most recently modified.

2.4 Business Value

This feature is essential for maintaining operational efficiency within the Lumi ERP. By providing a reliable and fast way to fetch product details, it ensures that staff members have immediate access to accurate pricing and service information. This reduces manual lookup time, minimizes errors in service delivery, and provides a seamless experience for users managing the service catalog.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/service_product_types

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature introduces a new way to create "Service Product Types" within the Lumi ERP system. Whether a user is adding a new type through a quick-entry pop-up window or the full management page, this tool ensures that the information is captured consistently and saved to the system database. It is designed to be flexible, requiring only a name to get started while automatically handling necessary financial settings in the background.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and authorized to perform this action.
2. Validation: The system checks that a name has been provided for the new service product type. If the name is missing, the request is rejected.
3. Applying Defaults: If specific financial details (such as the Service Advisor or Refund Account) are not provided, the system automatically assigns the company's standard default accounts to ensure the record is complete.
4. Status Assignment: If the "active" status is not specified, the system defaults the new entry to "active" so it is immediately available for use.
5. Saving: The system saves the new service product type to the database, assigning it a unique identifier and recording the creation time.
6. Confirmation: The system returns the newly created record to the user, confirming that the process was successful.

1.3 Key Concepts

- Service Product Type: A category used to organize and manage the different types of services offered by the business.
- Default Account Assignment: A smart feature that fills in required financial information automatically, reducing the amount of data entry required by the user.
- Validation: A safety check that ensures essential information (like the name) is present before the system attempts to save the data.
- Active Status: A toggle that determines whether a service product type is currently available for selection in the system.

1.4 Business Value

This feature streamlines the workflow for administrative and finance teams by providing a standardized method for categorizing services. By automating the assignment of default financial accounts, it reduces manual data entry errors and ensures that all service types are correctly linked to the company's financial records from the moment they are created. This consistency improves reporting accuracy and saves time for users who need to quickly add new service offerings.

2. Data

2.1 Overview

This feature introduces a new way for the system to create "Service Product Types." Whether a user is adding a quick service via a simple pop-up window or creating a detailed service type through the main management page, this tool ensures the information is captured, validated, and saved correctly in the system database.

2.2 Step-by-Step Flow

1. Receive Request: The system receives a request to create a new service product type.
2. Validate Input: The system checks that the request includes a valid "Name." If the name is missing or invalid, the request is rejected.
3. Apply Defaults: If optional details (such as the Service Advisor or Refund Account) are not provided—which is common when using the quick-add pop-up—the system automatically assigns the company's default financial account settings.
4. Save Data: The system records the new service product type in the database, including the name, description, financial account links, and its active status.
5. Confirm Success: Once saved, the system returns the newly created record, including its unique identification number, so the user interface can immediately display or use the new item.

2.3 Key Concepts

- Service Product Type: A category used to organize different services offered by the business.
- Chart of Accounts: A financial directory used by the system to ensure that services are linked to the correct accounting codes for reporting and refunds.
- Validation: A safety check performed by the system to ensure that required information (like the name of the service) is present before saving.
- Defaulting: An automated process where the system fills in missing optional information with pre-configured company standards to save the user time.

2.4 Business Value

This feature streamlines the service creation process by providing a flexible, reliable way to add new offerings to the system. By automating the assignment of financial accounts, it reduces manual data entry errors and ensures that all services are consistently categorized for accounting purposes, regardless of whether they were created through a quick shortcut or a detailed setup page.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/service_product_tags

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature introduces a new way to create "Service Product Tags" within the Lumi ERP system. These tags help categorize and organize service products. This functionality is designed to be flexible, supporting both quick-add actions (such as creating a tag directly while editing a product) and standard administrative tasks on the main Tags management page.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to perform the action.
2. Data Validation: The system checks that a name has been provided for the tag and that it is formatted correctly.
3. Uniqueness Verification: The system checks the existing list of tags to ensure the new name is not a duplicate.
4. Data Storage: If all checks pass, the system saves the new tag to the database with a unique identifier and a timestamp.
5. Confirmation: The system returns the details of the newly created tag (including its unique ID) so the user interface can immediately update to show the new tag.
6. Error Handling: If any step fails—such as an invalid name, a duplicate entry, or a system error—the user receives a clear message explaining why the tag could not be created.

1.3 Key Concepts

- Service Product Tag: A label used to categorize service products, making them easier to find and manage.
- Validation: The process of ensuring the information provided by the user meets the system's requirements (e.g., ensuring a name is not blank).
- Uniqueness Constraint: A business rule that prevents the system from having two tags with the exact same name, ensuring data remains clean and organized.
- Unique Identifier (ID): A permanent, system-generated code assigned to each tag to distinguish it from others, even if they have similar names.

1.4 Business Value

By providing a standardized way to create tags, this feature improves data consistency across the ERP. It streamlines the user experience by allowing staff to create new categories on the fly without leaving their current workflow, ultimately saving time and reducing the administrative burden of managing service product catalogs.

2. Data

2.1 Overview

This feature introduces a new way to create "Service Product Tags" within the Lumi ERP system. These tags help organize and categorize service products. This functionality is designed to be flexible, allowing users to create new tags on the fly—whether they are working within a specific service product form or managing the master list of tags in the system settings.

2.2 Step-by-Step Flow

1. Request Submission: The user initiates the creation of a new tag (e.g., by clicking "Save" in a "New Tag" modal).
2. Validation: The system checks that the request is properly formatted and that the required "Name" field is provided.
3. Uniqueness Check: The system verifies that a tag with the requested name does not already exist to prevent duplicate entries.
4. Persistence: If the name is unique and valid, the system saves the new tag to the database, automatically assigning it a unique identifier and a creation timestamp.
5. Confirmation: The system returns the newly created tag details (including its unique ID) to the user interface, allowing the application to immediately update dropdown menus or lists without requiring a page refresh.

2.3 Key Concepts

- Service Product Tag: A label used to categorize service products for better organization and reporting.
- Uniqueness Constraint: A rule ensuring that no two tags share the exact same name, keeping the system organized and preventing confusion.
- Unique Identifier (ID): A permanent, system-generated code assigned to each tag to ensure it can be reliably tracked and referenced by the software.
- Validation: The process of ensuring the information provided by the user meets the necessary requirements before it is saved to the database.

2.4 Business Value

- Improved Efficiency: Users can create new tags directly within the workflow (e.g., while editing a product), eliminating the need to navigate away to a separate settings page.
- Data Integrity: By enforcing unique names, the system prevents the creation of duplicate or ambiguous categories, ensuring clean and reliable reporting.
- Seamless User Experience: Because the system returns the new tag information immediately upon creation, the user interface can update dynamically, providing a smooth and responsive experience.

GET /api/service_products/:id/edit

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides the data necessary to load the "Edit Service Product" page in the Lumi ERP system. When a user selects a service product to edit, this process retrieves the existing details of that specific item and gathers all the necessary lists (such as categories, tax codes, and account options) required to populate the form's dropdown menus. This ensures that when the page opens, the fields are already filled with the correct information and the user has all available options ready to select.

1.2 Step-by-Step Flow

1. Locate the Record: The system receives a request for a specific service product ID and searches the database to find the corresponding record. If the record does not exist, the system returns an error message.
2. Gather Form Data: Once the record is found, the system collects the current saved values for that product. Simultaneously, it pulls the complete lists of available options for all form dropdowns, including service types, tags, tax codes, units of measure, and financial accounts.
3. Assemble and Send: The system combines the specific product details with the full set of dropdown options into a single package and sends it to the user's screen to display the pre-filled edit form.

1.3 Key Concepts

- Service Product: The specific item or service being managed within the ERP system.
- Lookup Data: The collection of pre-defined options (like tax codes or categories) that populate dropdown menus, ensuring users select valid, standardized information.
- Pre-filling: The process of automatically populating form fields with existing data so the user does not have to re-enter information that is already on file.
- Finance Module Integration: A connection to the financial system that ensures the edit form always displays the most current and accurate tax and accounting options.

1.4 Business Value

This feature streamlines the administrative workflow by eliminating manual data entry. By automatically pre-filling forms with existing data and providing accurate, up-to-date dropdown options, the system reduces the risk of human error, ensures consistency across financial records, and significantly speeds up the process of updating service product information.

2. Data

2.1

Overview

This feature provides the data necessary to populate the "Edit Service Product" screen in the Lumi ERP system. When a user selects a service product to edit, this tool retrieves the existing details for that specific item and gathers all the necessary lists (such as product types, tax codes, and units of measure) required to populate the form's dropdown menus. This ensures that the user sees the current information pre-filled and has all the correct options available to make updates.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to access the data.
2. Data Retrieval: The system locates the specific service product record using its unique ID. If the ID does not exist, the system returns a "Not Found" error.
3. Gathering Options: Simultaneously, the system collects all available dropdown choices, including service types, tags, tax product codes, and units of measure.
4. Form Assembly: The system combines the specific product's current information with the full list of available options.
5. Response: The system sends this complete package to the user's screen, allowing the edit form to display the current values and populate all selection menus.

2.3 Key Concepts

- Service Product: The core item being managed, which contains specific settings like tax codes, account associations, and categorization.
- Lookup Tables: The reference lists (such as tax codes or product types) that provide the standardized options for the form's dropdown menus.
- Pre-filling: The process of automatically populating form fields with existing data so the user does not have to re-enter information that is already on file.
- Unique Identifier (ID): A specific reference code used to ensure the system retrieves the exact product record requested by the user.

2.4 Business Value

This feature streamlines the administrative workflow by automating the preparation of the edit interface. By ensuring that all relevant data and valid selection options are loaded instantly, it reduces manual data entry errors, ensures consistency across the ERP system, and provides a seamless, responsive experience for users managing service products.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/service_products/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides the functionality for the "Save" button on the Edit Service Product page. It allows users to update the details of an existing service product, such as its name, price, tax settings, and associated tags. The system ensures data integrity by validating that all required information is provided and that the SKU remains unique within the company.

1.2 Step-by-Step Flow

1. Identify the Product: The system receives the request and locates the specific service product in the database using the provided ID. If the product does not exist, the process stops and returns an error.
2. Validate Input: The system checks that all mandatory fields (SKU, Name, Tax IDs, and Price) are present.
3. Check for Duplicates: The system verifies that the SKU provided is not already being used by another product within the same company.
4. Update Information: If all checks pass, the system updates the main product details in the database.
5. Sync Tags: The system clears the existing tags associated with the product and replaces them with the new list of tags provided in the update request.
6. Confirm Success: Once the changes are saved, the system returns the updated product information to confirm the operation was successful.

1.3 Key Concepts

- SKU Uniqueness: A business rule ensuring that every service product has a distinct identifier within a company to prevent inventory or billing confusion.
- Data Validation: A safety check performed before saving to ensure that no essential information is missing or incorrectly formatted.
- Tag Synchronization: The process of updating a list of labels or categories attached to a product by removing old ones and adding new ones to match the user's current selection.
- Transaction: A safety mechanism that ensures the product details and the associated tags are updated together; if one part fails, the entire update is rolled back to prevent data inconsistencies.

1.4 Business Value

This feature enables users to maintain accurate and up-to-date service catalogs. By enforcing SKU uniqueness and mandatory field validation, it prevents common data entry errors that could lead to billing or reporting issues. The seamless tag synchronization allows for flexible product categorization, ensuring that reporting and filtering remain accurate as business needs evolve.

2. Data

2.1 Overview

This feature provides the functionality for the "Save" button on the Edit Service Product page. It allows users to update the details of an existing service product—such as its name, price, tax settings, and associated tags—while ensuring that the data remains consistent and accurate within the system.

2.2 Step-by-Step Flow

1. Verification: The system first checks if the service product exists in the database. If it cannot be found, the process stops and notifies the user.
2. Business Rule Validation: The system checks the new SKU (Stock Keeping Unit) to ensure it is not already being used by another product within the same company. If a duplicate is found, the update is rejected.
3. Data Update: If all checks pass, the system updates the product's core information (like name and price) and refreshes the list of associated tags.
4. Tag Synchronization: The system removes any tags that were deselected and adds any new tags that were selected during the edit process.
5. Confirmation: Once the changes are successfully saved, the system returns the updated product details so the user can see the changes reflected immediately.

2.3 Key Concepts

- SKU Uniqueness: A business rule ensuring that every service product has a distinct identifier within a specific company to prevent inventory or billing confusion.
- Transaction: A safety mechanism that ensures the update is "all or nothing." If the system fails while updating the product or its tags, it will undo all changes to prevent partial or corrupted data.
- Tag Synchronization: The process of automatically matching the current list of tags in the database to the new list provided by the user, ensuring that removed tags are deleted and new ones are added.

2.4 Business Value

This feature ensures data integrity by preventing duplicate SKUs and maintaining accurate tag associations. By providing a reliable way to update service products, it allows businesses to keep their service catalogs current and organized without the risk of conflicting information or broken data links.

BUSINESS REQUIREMENTS DOCUMENT

Filter and Download Section

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Filter and Download feature provides a streamlined way for users to locate and extract specific service product information within the Lumi ERP system. By using a dedicated filter bar, users can narrow down large lists of products based on specific criteria and immediately export those results into a file for offline use or reporting.

1.2 Step-by-Step Flow

1. Input Criteria: Users enter search terms into the SKU, Name, or Tag fields, or select a specific category from the Type dropdown menu.
2. Real-time Validation: As the user types, the system automatically checks the input to ensure it meets length requirements (e.g., preventing overly long entries for SKU or Name fields).
3. Refining the List: Once the desired criteria are entered, the user clicks the "Search" button to update the displayed list of service products based on the selected filters.
4. Exporting Data: After the list has been narrowed down, the user clicks the "Download" button to generate a file containing only the items currently visible in the filtered list.

1.3 Key Concepts

- Filter Bar: A set of input fields that allows users to define specific parameters to narrow down a large dataset.
- Real-time Validation: A safety feature that checks the data as it is entered to prevent errors, such as exceeding character limits, before the search is even performed.
- Data Export: The ability to take the current, filtered view of the data and save it as a separate file for external use.
- Search Execution: The action of applying the chosen filters to the system database to retrieve a precise subset of service products.

1.4 Business Value

This feature improves operational efficiency by allowing staff to quickly find relevant service products without manually scanning through entire catalogs. By integrating the "Download" function directly with the filter results, users can generate custom reports or data exports on demand, ensuring that the information they extract is always consistent with the specific criteria they have defined.

BUSINESS REQUIREMENTS DOCUMENT

Add Page - Tax Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Tax Card is a dedicated section within the "Add Service Product" page designed to help users accurately configure tax settings for their services. It provides a structured interface to select primary and secondary taxes, define measurement units, and assign specific accounting codes required for financial reporting and tax compliance (such as PPN and PPh 23).

1.2 Step-by-Step Flow

1. Header Display: The section is clearly identified by a "% TAX" label at the top.
2. Primary Tax Selection: The user selects the main tax (e.g., PPN) from a dropdown menu. This field is mandatory.
3. Secondary Tax Selection: The user selects the "Other Tax" (e.g., PPh 23) from a second mandatory dropdown menu.
4. Measurement & Classification: The user optionally selects the "Tax Unit of Measure" and the "Tax Product Code" (used for e-faktur reporting) to further define the service.
5. Accounting Configuration: The system automatically defaults the "Other Tax Account" and "Other Tax Refund Account" to the PPh 23 account (100.104.003), though these can be adjusted if necessary.
6. Validation: If the user attempts to leave the primary or secondary tax fields empty, the system will display an error message to ensure all required information is captured before saving.

1.3 Key Concepts

- Tax: The primary tax applied to the service, such as Value Added Tax (PPN).
- Other Tax: A secondary tax category, specifically used here for withholding taxes like PPh 23.
- Tax Unit of Measure: The standard unit used to calculate or report the tax for the service.
- Tax Product Code: A specific code required for electronic tax invoicing (e-faktur) to ensure compliance.
- Tax Accounts: The specific ledger accounts where tax liabilities and refunds are recorded; these are pre-filled to save time and reduce manual entry errors.

1.4 Business Value

This feature streamlines the service creation process by centralizing all tax-related configurations in one place. By providing mandatory fields for primary and secondary taxes and pre-filling accounting codes, the system reduces the risk of human error, ensures consistent financial data, and helps the business remain compliant with local tax reporting requirements (e-faktur).

BUSINESS REQUIREMENTS DOCUMENT

Add Page - Info Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Info Card" is the primary data entry component for the Add Service Product page. It allows users to define the core identity of a service, including its name, unique identifier (SKU), classification, and descriptive details. The component is designed to ensure data quality by providing immediate feedback if required fields are left blank.

1.2 Step-by-Step Flow

1. Enter Basic Details: The user fills in the Service Name and SKU. The system validates these fields in real-time; if they are left empty, an error message appears to prompt the user.
2. Select Classification: The user selects a service type from a dropdown menu. If the desired type does not exist, the user can click the "+ New Type" button to open a pop-up window to create a new one.
3. Apply Tags: The user selects relevant tags from a list. If a new tag is needed, the user can click the "+ New Tag" button to open a pop-up window to create it.
4. Add Description: The user provides any additional context or details about the service in the description text area.
5. Save Auxiliary Data: When creating a new Type or Tag via the pop-up windows, the user enters the necessary details and saves, which updates the available options in the main form.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique alphanumeric code used to identify and track a specific service product.
- Validation: An automated check that ensures essential information (like Name and SKU) is provided before the user proceeds, preventing incomplete data entry.
- Auxiliary Entities: Supporting categories (Types and Tags) that help organize and filter services.
- Modal: A pop-up window that allows the user to perform a secondary task (like creating a new tag) without leaving the main page or losing their current progress.

1.4 Business Value

This feature streamlines the service creation process by centralizing all essential information in one place. By including real-time validation, it reduces data entry errors, ensuring that every service is properly identified and categorized from the start. Furthermore, the ability to create new Types and Tags on the fly prevents workflow interruptions, allowing users to maintain productivity without needing to navigate to separate administrative settings pages.

BUSINESS REQUIREMENTS DOCUMENT

Add Page - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Settings Card is a configuration component within the "Add Service Product" page. It allows users to define key operational behaviors for a new service, such as its availability status, pricing flexibility, and duration expectations. This ensures that each service is correctly categorized and behaves as expected when used in future transactions.

1.2 Step-by-Step Flow

1. Set Active Status: By default, the service is marked as "Active." You can toggle this off if you wish to create the service in the system without making it immediately available for use.
2. Configure Pricing: You can enable the "Open Price" option. When active, this allows staff to manually set or change the price of the service at the moment of a transaction, rather than relying on a fixed price.
3. Define Duration: You can enter an "Estimated Time" (in minutes) to indicate how long the service typically takes. The system will validate this input to ensure only positive numbers are entered.
4. Configure Duration Flexibility: You can enable "Open Estimated Time." Similar to open pricing, this allows the duration of the service to be adjusted freely during a transaction, providing flexibility for services that vary in length.

1.3 Key Concepts

- Active Status: A toggle that determines if a service is currently available for selection in the system.
- Open Price: A setting that permits the final price of a service to be determined at the time of sale rather than being pre-set.
- Estimated Time: A numeric field used to set the standard duration of a service, helping with scheduling and planning.
- Open Estimated Time: A setting that allows the duration of a service to be modified at the time of sale to accommodate variable work requirements.

1.4 Business Value

This feature provides the necessary flexibility to manage diverse service offerings within the ERP. By allowing users to define whether prices and durations are fixed or "open," the system can support both standardized services (like a flat-rate haircut) and variable services (like custom consulting or repair work). This reduces manual workarounds and ensures that service data remains accurate and consistent across the platform.

BUSINESS REQUIREMENTS DOCUMENT

Add Page - Store Pricing Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Store Pricing Card is a user interface component designed for the "Add Service Product" page within the Lumi ERP system. It provides a dedicated section where users can define the financial details of a service, specifically setting the price in Indonesian Rupiah (IDR) and indicating whether that price already includes tax.

1.2 Step-by-Step Flow

1. Section Identification: The user views the "Store Pricing" section, clearly marked with a blue label to distinguish it from other product details.
2. Price Entry: The user enters the service cost into the "Price (IDR)" field.
3. Real-time Validation: As the user types, the system immediately checks that the input is a valid, positive number. If the entry is invalid or empty, an error message appears to guide the user.
4. Tax Specification: The user toggles the "Including Tax" checkbox. By default, this is unchecked, but the user can select it to confirm that the entered price is inclusive of tax.

1.3 Key Concepts

- Price (IDR): The primary input field for defining the cost of the service, which requires a positive numerical value to ensure accurate financial data.
- Real-time Validation: A feature that provides instant feedback to the user while they are typing, preventing submission errors before they happen.
- Tax Inclusion Toggle: A simple checkbox that allows the business to clarify the tax status of the service price, ensuring transparency in pricing.

1.4 Business Value

This feature streamlines the service creation process by providing a clear, standardized way to input pricing information. By including built-in validation, the system reduces data entry errors, ensuring that financial records remain accurate. Additionally, the tax toggle provides necessary flexibility for different service pricing models, helping the business maintain compliance and clarity in their service offerings.

BUSINESS REQUIREMENTS DOCUMENT

Detail Page - Info Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Product Info Card is a clean, read-only display component designed for the Lumi ERP system. Its primary purpose is to provide a quick, organized summary of a specific service product's core information. By presenting these details in a structured layout, users can easily reference essential product data without the risk of accidental changes.

1.2 Step-by-Step Flow

1. Header Display: The card begins with a "DETAILS" header, marked by a blue badge and a document icon to clearly identify the section.
2. Name: The system displays the official name of the service product.
3. Tags: The system lists relevant categories or labels associated with the product, styled as distinct, dark-colored badges for quick visual scanning.
4. Type: The system shows the specific classification or type of the service product.
5. Description: The system provides a detailed summary or explanation of what the service product entails.
6. SKU: The system displays the unique Stock Keeping Unit (SKU) code used for inventory and identification purposes.

1.3 Key Concepts

- Read-Only: Information is presented for viewing purposes only; users cannot edit or modify these fields directly within this component.
- Pill Badge: A visual design element used for tags, allowing multiple categories to be grouped together in a compact, easy-to-read format.
- SKU: A unique identifier assigned to a service product to help track it within the ERP system.
- Info Grid: A structured layout that aligns labels with their corresponding data, ensuring the information is easy to scan and understand.

1.4 Business Value

This feature improves operational efficiency by providing a standardized way to view service product details. By centralizing key information—such as the SKU, type, and description—in a consistent format, staff can quickly verify product specifications during daily tasks. The read-only nature of the card ensures data integrity, preventing unauthorized or accidental modifications while maintaining a clean and professional user interface.

BUSINESS REQUIREMENTS DOCUMENT

Detail Page - Store Pricing

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Store Pricing component is a dedicated section within the Lumi ERP service product detail page. Its purpose is to provide clear, at-a-glance visibility into the pricing structure of a specific service, ensuring that users can easily distinguish between the base price and the final price including taxes.

1.2 Step-by-Step Flow

1. Header Display: The component displays a "STORE PRICING" label in blue, accompanied by a dollar icon, to clearly identify the section.
2. Data Retrieval: The system pulls the base price and the tax-inclusive price associated with the specific service product.
3. Currency Formatting: The system automatically formats these numerical values into the local currency (IDR) to ensure consistency and readability.
4. Final Presentation: The component displays the base price followed by the tax-inclusive amount in parentheses (e.g., "Rp 100.000 (Rp 110.000 Inc Tax)") within a clean, bordered card layout.

1.3 Key Concepts

- Base Price: The standard cost of the service before any additional tax calculations are applied.
- Tax-Inclusive Price: The final amount a customer pays, which includes all applicable taxes.
- Currency Formatting: A standardized way of displaying monetary values (using the IDR format) to ensure the information is professional and easy for the user to interpret.
- Read-Only Display: The pricing information is presented for informational purposes only and cannot be edited directly within this specific component.

1.4 Business Value

This feature improves transparency for users by providing immediate clarity on service costs. By explicitly showing both the base price and the tax-inclusive total, the system reduces potential confusion regarding final costs, helps users make informed decisions, and ensures that financial information is presented in a consistent, professional format across the Lumi ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

Detail Page - Changes Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Changes Card" is a dedicated information panel located on the service product detail page. Its purpose is to provide transparency and accountability by displaying a clear audit trail of who created or modified a specific record and when those actions took place.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "CHANGES" label accompanied by a clock icon to signify that the information relates to the record's history.
2. Creation Details: The system displays the name and email address of the user who originally created the record, followed by the exact date and time of creation.
3. Update Details: The system displays the name and email address of the user who most recently modified the record, followed by the exact date and time of that last update.

1.3 Key Concepts

- Audit Trail: A chronological record of activities that provides evidence of who performed an action and when it occurred.
- Read-Only Fields: Information presented for viewing purposes only; these fields cannot be edited by the user, ensuring the integrity of the historical data.
- User Identification: A combined display format that shows both the full name and email address of a user to ensure there is no ambiguity regarding who performed an action.
- Standardized Timestamp: A consistent date and time format (e.g., 09-Jun-2024 09:40 PM) used to ensure clarity across all records.

1.4 Business Value

- Accountability: By clearly identifying who created or updated a service product, the organization can easily track responsibility for data entries.
- Transparency: Users can quickly verify the age and maintenance status of a record without needing to consult external logs or administrative reports.
- Improved Troubleshooting: If data discrepancies arise, the audit trail allows team members to identify exactly when a change occurred and who to contact for clarification.

BUSINESS REQUIREMENTS DOCUMENT

Detail Page - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Settings Card" is a read-only information panel located on the Service Product detail page. Its purpose is to provide a quick, at-a-glance summary of the operational and pricing configurations for a specific service. By using clear visual indicators, it allows staff to immediately understand how a service is set up without needing to navigate through complex menus.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "SETTINGS" header accompanied by a gear icon to clearly identify the section.
2. Active Status: The system shows whether the service is currently active, using a green checkmark for "Yes" or a red mark for "No."
3. Open Estimated Time Status: The system indicates if the service duration is flexible ("Open") or fixed, using the same green/red visual status indicators.
4. Estimated Time Value: The system displays the specific duration of the service in minutes.
5. Open Price Status: The system indicates if the service price is flexible ("Open") or fixed, using the green/red visual status indicators.

1.3 Key Concepts

- Read-Only: Information is displayed for viewing purposes only and cannot be modified directly within this specific card.
- Status Indicators: Visual cues (green checkmarks for "Yes" and red marks for "No") that allow users to instantly interpret the configuration state of a service.
- Open vs. Fixed: A distinction used for time and pricing; "Open" implies the value is flexible or variable, while "Fixed" implies a set, predetermined value.

1.4 Business Value

This feature improves operational efficiency by reducing the time staff spend searching for core service details. By centralizing these key settings in a standardized, easy-to-read format, the team can quickly verify service parameters, minimize errors during customer interactions, and ensure that service delivery aligns with the current configuration.

BUSINESS REQUIREMENTS DOCUMENT

Detail Page - Tax Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Tax Card is a dedicated information panel within the Service Product detail page. Its purpose is to provide a clear, read-only summary of all tax-related configurations associated with a specific service product. This ensures that users can quickly verify tax settings without needing to navigate through complex configuration menus.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "TAX" badge accompanied by a percentage icon to clearly identify the section.
2. Primary Tax Information: The system retrieves and displays the main tax name, the tax unit of measure, and the specific tax product code.
3. Secondary Tax Information: The system retrieves and displays details regarding "Other Tax" configurations, including the tax name, the associated tax account, and the tax refund account.
4. Data Presentation: All fields are presented in a clean, read-only format. If a specific piece of information has not been set for the product, the system will display a dash (-) to indicate that the field is empty.

1.3 Key Concepts

- Read-Only: Information is displayed for reference purposes only and cannot be modified directly within this view.
- Service Product Entity: The central data source that holds all the tax configuration details for a specific service.
- Placeholder Logic: A standard behavior where empty or missing data is represented by a dash, ensuring the interface remains consistent and readable.

1.4 Business Value

- Improved Transparency: Provides immediate visibility into tax settings, reducing the time spent searching for compliance-related information.
- Error Reduction: By surfacing tax product codes and account labels clearly, users can easily verify that the correct tax settings are applied to a service before processing transactions.
- User Experience: Consolidates fragmented tax data into a single, organized component, making the Service Product detail page easier to navigate and understand.

BUSINESS REQUIREMENTS DOCUMENT

Edit Page - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Settings Card is a configuration interface within the Lumi ERP system designed to help you manage the core attributes of a service product. This component allows you to quickly toggle service availability, pricing flexibility, and time estimates, ensuring that your service catalog remains accurate and easy to update.

1.2 Step-by-Step Flow

1. Active Status: You can toggle the "Active" checkbox to enable or disable the service product. The system will show the current status by default.
2. Open Price: You can toggle the "Open Price" checkbox to indicate if the service price is flexible or negotiable.
3. Estimated Time: You can enter the expected duration for the service in minutes. The system validates this input in real-time; if you enter a negative number or an invalid format, an error message will appear to ensure the data remains accurate.
4. Open Estimated Time: You can toggle the "Open Estimated Time" checkbox to indicate if the service duration is flexible or subject to change.

1.3 Key Concepts

- Active: A status indicator that determines if the service is currently available for selection or booking.
- Open Price: A setting that signals that the price for this service is not fixed and may be determined at the time of sale.
- Estimated Time: The expected duration of the service, measured in minutes, used for scheduling and planning purposes.
- Open Estimated Time: A setting that signals that the duration of the service is flexible or variable rather than fixed.
- Real-time Validation: An automated check that immediately alerts you if the information entered (such as duration) does not meet the required criteria.

1.4 Business Value

This feature streamlines the management of service products by providing a centralized, intuitive interface for configuration. By including real-time validation for time estimates, the system prevents data entry errors, ensuring that scheduling and pricing reports remain reliable. This allows your team to maintain an up-to-date service catalog with minimal effort and reduced risk of operational errors.

BUSINESS REQUIREMENTS DOCUMENT

Edit Page - Store Pricing

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Store Pricing feature provides a dedicated section within the service product setup page, allowing users to define and manage how a service is priced for the store. This interface ensures that pricing information is clear, accurate, and easy to update, helping maintain consistent financial data across the platform.

1.2 Step-by-Step Flow

1. View Pricing Details: When opening the service product page, the system displays the current price and tax status in the "Store Pricing" section, marked by a blue header and a dollar icon.
2. Update Price: The user enters or modifies the service cost in the "Price (IDR)" field. The system automatically checks that the value is a valid, positive number.
3. Toggle Tax Status: The user can check or uncheck the "Including Tax" box to indicate whether the entered price already accounts for tax.
4. Validation: If an invalid price (such as a negative number) is entered, the system immediately alerts the user so they can correct the entry before saving.

1.3 Key Concepts

- Price (IDR): The numerical value representing the cost of the service, which must be a positive number.
- Including Tax: A toggle setting that clarifies if the displayed price is inclusive of tax or if tax should be calculated separately.
- Real-time Validation: A safety feature that checks the price input as the user types to prevent errors from being submitted to the system.

1.4 Business Value

- Data Accuracy: By enforcing positive number validation, the system prevents common data entry errors that could lead to incorrect billing or financial reporting.
- Improved User Experience: Providing a clear, dedicated section for pricing reduces confusion during the product setup process.
- Operational Flexibility: The tax toggle allows the business to adapt to different regional pricing requirements or service models without needing additional software changes.

Edit Page - Tax Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Tax Card is a dedicated section within the Service Product edit page designed to manage all tax-related settings for a specific service. It provides a centralized interface where users can select primary and secondary tax types, as well as define specific accounting and reporting codes required for tax compliance.

1.2 Step-by-Step Flow

1. Header Identification: The user identifies the section by the "TAX" label and the percent (%) icon located at the top of the card.
2. Primary Tax Selection: The user selects the main tax type (e.g., PPN) from a required dropdown menu.
3. Secondary Tax Selection: The user selects the secondary tax type (e.g., PPh 23) from a second required dropdown menu.
4. Optional Configuration: The user may optionally populate additional fields to ensure accurate financial reporting:

* Tax Product Code: Selects the appropriate e-Faktur code.

* Tax Unit of Measure: Defines the unit associated with the tax calculation.

* Other Tax Account: Selects the specific Chart of Accounts entry for the secondary tax.

* Other Tax Refund Account: Selects the specific Chart of Accounts entry for secondary tax refunds.

5. Validation: The system automatically checks that both the "Tax" and "Other Tax" fields are filled. If these mandatory fields are empty, the form will be flagged as incomplete.

1.3 Key Concepts

- Mandatory Fields: The "Tax" and "Other Tax" fields are required; the form cannot be considered complete without these selections.
- Dropdown Selection: All inputs use a standardized selection list, allowing users to either choose from existing data or clear their selection if needed.
- Pre-selection: To improve efficiency, the system automatically loads existing tax settings if they have been previously configured for the service product.
- Real-time Validation: The system monitors the status of the mandatory fields instantly as the user makes changes, ensuring data integrity without requiring a manual "save" to trigger a check.

1.4 Business Value

- Compliance: By mandating the selection of primary and secondary taxes, the system ensures that all service products are correctly categorized for tax reporting purposes.
-

Efficiency: Pre-loading existing tax data reduces manual data entry and minimizes the risk of human error when editing service products.

- Standardization: Providing specific fields for tax product codes and accounting accounts ensures that financial data is consistent across the entire ERP system, simplifying the reconciliation process for the accounting team.

BUSINESS REQUIREMENTS DOCUMENT

Edit Page - Info Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Product Info Card is the primary interface for viewing and updating the core details of a service product within the Lumi ERP system. This component provides a user-friendly form that allows staff to manage essential product information, such as its classification, identification codes, and descriptive metadata, ensuring that service records remain accurate and up-to-date.

1.2 Step-by-Step Flow

1. Load Existing Data: When the page opens, the form is automatically populated with the current details of the service product (Type, Name, SKU, Description, and Tags).
2. Edit Fields: Users can modify the Name, SKU, and Description directly. The system performs real-time validation to ensure that mandatory fields like Name and SKU are not left empty.
3. Manage Type: Users can select a service type from a dropdown menu. If the required type is missing, they can click the "New Type" button to open a pop-up window, create a new category, and immediately apply it to the current product.
4. Manage Tags: Users can view existing tags as removable chips. They can add new tags via a multi-select menu or click the "New Tag" button to create and add a brand-new tag on the fly.
5. Real-time Feedback: As the user types or changes selections, the system immediately checks for errors and displays alerts if required information is missing.

1.3 Key Concepts

- SKU (Stock Keeping Unit): A unique identifier used to track specific services within the system.
- Real-time Validation: A feature that checks for errors (such as missing required fields) the moment a user interacts with a field, providing instant feedback.
- Dynamic Creation: The ability to create new "Types" or "Tags" directly from the edit screen without needing to navigate away to a separate settings page.
- Multi-select Tags: A flexible way to categorize services by applying multiple labels, which can be easily added or removed as needed.

1.4 Business Value

- Data Integrity: By enforcing mandatory fields like Name and SKU in real-time, the system prevents incomplete or invalid data from being saved.
- Operational Efficiency: The ability to create new categories (Types and Tags) directly within the edit screen reduces administrative friction, allowing users to maintain their product catalog without interrupting their workflow.

- User Experience: The pre-filled form and intuitive controls (like removable chips and clear error messaging) minimize manual data entry effort and reduce the likelihood of user error.

BUSINESS REQUIREMENTS DOCUMENT

Product List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Product List feature allows you to define which specific products are eligible for a voucher. You can manage these products in two ways: by selecting them individually from a list or by uploading a file to add a large number of products at once. This ensures flexibility whether you are applying a voucher to a single item or an entire catalog.

1.2 Step-by-Step Flow

1. Accessing the Selection: When you choose the "By Product List" option for a voucher, the product selection area becomes available.
2. Individual Selection: You can manually pick specific products from the provided list to include in your voucher.
3. Downloading a Template: If you have many products to add, you can click the "Download Example File" link to get a template. This file shows you exactly how to format your data so the system can read it correctly.
4. Bulk Uploading: Once your file is ready, click the "Upload Products" button to select your document. The system will automatically process the file and add the products to your voucher.
5. Validation: The system checks your file during the upload process to ensure it is in the correct format (CSV or Excel) before adding the items.

1.3 Key Concepts

- Bulk Upload: A time-saving feature that allows you to import a list of products from a file rather than adding them one by one.
- Sample Template: A pre-formatted file provided by the system that acts as a guide to ensure your data is uploaded successfully without errors.
- Product Selection Field: The primary interface where you view and manage the specific items currently assigned to a voucher.

1.4 Business Value

This feature significantly reduces manual data entry time for users managing large-scale promotions. By providing a standardized template and a bulk upload option, it minimizes human error and ensures that voucher application is accurate, efficient, and scalable, regardless of the number of products involved.

BUSINESS REQUIREMENTS DOCUMENT

Product Type and Brand

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

This feature introduces a dynamic selection tool within the Lumi ERP voucher configuration. It allows users to precisely target vouchers by specifying a particular product category and brand. To keep the interface clean and intuitive, these options only appear when the user explicitly chooses to apply a voucher based on product type and brand.

1.2 Step-by-Step Flow

1. Triggering the Fields: The user selects "By Product Type and Brand" from the main Product Condition dropdown.
2. Displaying Options: Once the condition is selected, the system automatically reveals the "Product Type" and "Product Brand" dropdown menus.
3. Making Selections: The user chooses the desired product type and brand from the available lists.
4. Real-time Validation: As the user makes their selections, the system immediately checks that both fields are filled. If a field is left blank, an error message appears to prompt the user to complete the information.

1.3 Key Concepts

- Conditional Visibility: A design approach where specific input fields are hidden by default and only appear when they are relevant to the user's current task.
- Immediate Validation: A feedback mechanism that alerts the user to missing information as soon as they interact with the form, rather than waiting until they try to save the entire voucher.
- Voucher Targeting: The process of defining specific criteria (in this case, type and brand) to ensure a voucher is only applied to the intended products.

1.4 Business Value

This feature enhances the precision of your promotional and discount strategies. By allowing users to restrict vouchers to specific product types and brands, the business can run more targeted marketing campaigns, manage inventory promotions more effectively, and reduce the risk of vouchers being applied to unintended items. The real-time validation ensures that all voucher configurations are complete and accurate before they are finalized, preventing errors in the sales process.

BUSINESS REQUIREMENTS DOCUMENT

Voucher Details JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Voucher Details feature provides a standardized way for the system to retrieve and display comprehensive information about a specific voucher. By combining voucher data with relevant product details, the system ensures that users receive a complete, easy-to-read summary of a voucher's status, value, and associated product information in a single request.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view a specific voucher using its unique identifier.
2. Data Retrieval: The system searches the database for the requested voucher.
3. Information Consolidation: During the search, the system automatically links the voucher to its corresponding product record to pull in descriptive details like the product name and SKU.
4. Data Formatting: The gathered information is organized into a predefined structure (a "schema") to ensure all necessary fields—such as pricing, validity dates, and current status—are presented consistently.
5. Response Delivery: The final, structured package of information is delivered to the user or application interface.

1.3 Key Concepts

- Voucher: A digital record representing a discount or credit, containing details like its type, monetary value, and validity period.
- Product Metadata: Essential information about the item the voucher applies to, specifically the product name and SKU, which are pulled in automatically to provide context.
- Schema: A blueprint that defines exactly what information is included in the response, ensuring that every voucher detail is presented in the same format every time.
- Status Tracking: Indicators that define the current state of a voucher, such as whether it is active, inactive, or expired.

1.4 Business Value

- Improved Data Accuracy: By enforcing a strict structure for voucher information, we eliminate inconsistencies in how data is displayed across the platform.
- Operational Efficiency: Users no longer need to look up product details separately; the system automatically joins this information, saving time and reducing manual effort.
- Better Decision Making: Providing clear, consolidated data—such as validity dates and pricing—allows staff to quickly verify voucher eligibility and status, leading to faster customer service and more reliable reporting.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The `GET /api/customers` feature provides a flexible way for external systems to retrieve a list of customers from the Lumi ERP database. It is designed to handle large volumes of data by allowing users to filter, search, sort, and paginate results, ensuring that applications only receive the specific information they need at any given time.

1.2 Step-by-Step Flow

1. Validation: The system checks the incoming request to ensure that any sorting or customer type filters provided are valid and supported.
2. Type Filtering: The system identifies the specific category of customer requested (e.g., retail, wholesale, franchise, or consignment) based on internal business rules.
3. Specific Filtering: The system applies any additional filters provided, such as searching for a specific customer group, tax number, phone number, or active status.
4. General Search: If a general search term is provided, the system scans key fields (like name, code, or email) to find matching records.
5. Sorting: The system organizes the results based on the user's preference (e.g., by name or code). If no preference is given, it defaults to showing the most recently created customers first.
6. Pagination: To keep performance high, the system calculates the total number of matching records and returns only a specific "page" of results (a limited number of records starting from a specific point).
7. Response: The system returns the requested list of customers along with metadata, such as the total count of records found, to help the calling application manage the data display.

1.3 Key Concepts

- Filtering: The ability to narrow down the customer list by specific attributes, such as their assigned store, salesperson, or active status.
- Search: A broad lookup feature that checks multiple fields (like name and phone number) simultaneously to find a customer when you don't have a specific ID.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve system speed and user experience.
- Sorting: The process of arranging the customer list in a specific order, such as alphabetically by name or numerically by customer code.

1.4 Business Value

This feature empowers integrated applications to efficiently access customer data without overloading the system. By providing robust filtering and pagination, it ensures that sales teams, support staff, and automated systems can quickly retrieve accurate customer information, which is essential for maintaining smooth operations and high-quality customer service within the Lumi ERP ecosystem.

2. Data

2.1 Overview

The Customer API feature provides a flexible way to retrieve a list of customers from the Lumi ERP system. It is designed to help users quickly find specific customer records by allowing them to filter, search, and sort the data. The system also includes pagination to ensure that large lists of customers are delivered in manageable chunks, improving performance and usability.

2.2 Step-by-Step Flow

1. Initiate Request: The system receives a request to fetch the customer list.
2. Filter by Type: The system checks if a specific customer category (Retail, Wholesale, Franchise, or Consignment) is requested and narrows the results accordingly.
3. Apply Specific Filters: The system applies any additional criteria provided, such as filtering by a specific store, salesperson, or active status.
4. Perform Search: If a general search term is provided, the system scans key fields (like name, email, or phone number) to find matching records.
5. Sort Results: The system organizes the list based on the user's preference (e.g., by name or customer code). If no preference is given, it defaults to showing the most recently created customers first.
6. Paginate and Return: The system calculates the total number of matching records and returns a specific "page" of data based on the requested limit and offset.

2.3 Key Concepts

- Filtering: Narrowing down the list based on specific attributes, such as customer type or active status.
- General Search: A broad search function that looks for a keyword across multiple fields simultaneously, such as name, email, or tax number.
- Sorting: Organizing the final list in a specific order (ascending or descending) based on fields like name or group.
- Pagination: A method of breaking a large dataset into smaller, numbered pages to make the information easier to navigate and faster to load.

2.4 Business Value

This feature empowers users to efficiently manage and access customer data. By providing robust search and filtering capabilities, staff can quickly locate the exact customer information they need without manually sifting through the entire database. Furthermore, the pagination and sorting features ensure that the application remains fast and responsive, even as the customer database grows over time.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers/franchise

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a secure way to retrieve a filtered list of customers specifically identified as franchises within the Lumi ERP system. By using this tool, authorized users can quickly pull essential contact and identification details for all franchise-type accounts, ensuring that franchise-related data is easily accessible for reporting and management purposes.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the person or application requesting the data is logged in and identified.
2. Permission Check: The system confirms that the user has the specific security clearance required to view franchise-related customer information.
3. Data Retrieval: The system searches the customer database and filters for records specifically marked as franchises.
4. Data Delivery: The system compiles the relevant details—such as name, email, and franchise ID—and sends them back to the user.
5. Error Handling: If any step fails (such as a lack of permission or a system error), the system provides a clear notification explaining why the request could not be completed.

1.3 Key Concepts

- Franchise Customer: A specific category of customer within the ERP system that is flagged for unique management and reporting.
- Authentication: The process of verifying the identity of the user to ensure they are who they claim to be.
- Authorization: The process of checking if an authenticated user has the specific "permission" required to access sensitive franchise data.
- Data Filtering: The automated process of narrowing down the entire customer list to show only those that meet the "franchise" criteria.

1.4 Business Value

This feature streamlines operations by allowing staff to instantly generate a list of franchise partners without manual searching or data manipulation. It enforces strict security protocols, ensuring that only authorized personnel can access sensitive franchise information, which helps maintain data integrity and compliance across the organization.

2. Data

2.1 Overview

This feature provides a dedicated way for the Lumi ERP system to retrieve a filtered list of customers who are specifically classified as "franchise" partners. By using this endpoint, the system can quickly isolate franchise-related accounts from the general customer database, ensuring that users only see the relevant business entities they are authorized to access.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to fetch the list of franchise customers.
2. Authentication & Authorization Check: The system verifies that the user is logged in and has the necessary permissions to view franchise-level data. If the user is not authorized, the request is blocked.
3. Data Filtering: The system queries the customer database, applying a specific filter to include only those records marked as a franchise.
4. Response Delivery:

* If successful, the system returns the list of franchise customers.

* If the request is malformed, unauthorized, or if a server error occurs, the system returns an appropriate error message to explain why the data could not be retrieved.

2.3 Key Concepts

- Franchise Customer: A specific category of customer within the ERP system that operates under a franchise model, distinguished from standard individual or corporate customers.
- Filtering: The process of narrowing down a large database of customers to show only those that meet the "franchise" criteria.
- Authorization: A security check that ensures only users with the correct access rights can view sensitive franchise data.
- Endpoint: A specific digital "address" in the software that allows other parts of the system to request this specific list of franchise customers.

2.4 Business Value

This feature streamlines operations for teams managing franchise networks by providing an automated, reliable way to pull franchise-specific data. It reduces manual effort and potential errors by ensuring that the system automatically handles the filtering logic, while simultaneously maintaining data security by enforcing strict access controls for franchise information.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers?{filters}&{pagination}&{sorting}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Customer Search feature provides a flexible way to retrieve a list of customers from the Lumi ERP system. By using specific search criteria, you can quickly narrow down your customer database to find exactly who you are looking for. The system is designed to handle large amounts of data efficiently by breaking results into manageable pages and allowing you to sort the information in a way that best suits your workflow.

1.2 Step-by-Step Flow

1. Authentication Check: The system first verifies that you have the necessary permissions to access customer data. If you are not logged in or your session is invalid, the request will be denied.
2. Parameter Validation: The system checks your search request to ensure it includes the required "type" category. If the request is missing this or contains invalid information, the system will notify you of the error.
3. Applying Filters: The system applies your specific search criteria (such as name, status, phone, or email) to narrow down the list of customers.
4. Sorting and Organization: The system organizes the results based on your preferred field (e.g., by name or date created) and order (ascending or descending). If no preference is provided, it defaults to sorting by the date the customer was added.
5. Pagination: To keep the data easy to read, the system divides the results into pages. You can specify which page you want to view and how many customers should appear on each page.
6. Data Retrieval: The system gathers the matching records and presents them to you. If no customers match your search criteria, the system will inform you that no results were found.

1.3 Key Concepts

- Filters: Specific criteria used to narrow down search results, such as searching for a customer by their email address or account status.
- Pagination: A method of splitting a large list of results into smaller, manageable chunks (pages) to improve performance and readability.
- Sorting: The ability to arrange the final list of customers in a specific order, such as alphabetically by name or chronologically by creation date.
- Mandatory Field: A required piece of information (in this case, "type") that must be included in your search request for the system to process it.

1.4 Business Value

This feature significantly improves operational efficiency by allowing staff to locate customer records instantly without manually scrolling through long lists. By providing robust filtering and sorting capabilities, the system ensures that users can access the exact data they need for reporting, communication, or account management. Furthermore, the pagination logic ensures that the application remains fast and responsive, even as the customer database grows over time.

2. Data

2.1 Overview

The Customer Search feature provides a flexible way to retrieve lists of customers from the system. It allows users to narrow down results using specific criteria (such as name, status, phone, or email), organize the data in a preferred order, and view the results in manageable chunks (pagination). This ensures that even with a large database, users can quickly find the specific information they need without overwhelming the system.

2.2 Step-by-Step Flow

1. Request Validation: The system receives the search request and first checks that a "customer type" is provided, as this is a mandatory requirement for the search.
2. Base Filtering: The system identifies the core group of customers based on the required "type."
3. Applying Search Criteria: The system applies any additional filters provided (e.g., searching for a specific name or email). It only processes filters for approved fields to ensure data security and accuracy.
4. Counting Results: Before returning the data, the system calculates the total number of customers that match the search criteria. This helps the user understand the full scope of their search results.
5. Sorting: The system organizes the list based on the user's preferred field (e.g., by name or creation date) and direction (ascending or descending).
6. Pagination: The system slices the list into smaller pages based on the requested page number and the number of items per page, then returns the final list along with the total count metadata.

2.3 Key Concepts

- Filters: Specific criteria used to narrow down the list, such as searching by name, status, phone number, or email address.
- Pagination: A method of breaking a large list of results into smaller, manageable pages (e.g., 20 items per page) to improve performance and readability.
- Sorting: The ability to arrange the results in a specific order, such as alphabetical order or by the date the customer was added.

- Metadata: Additional information returned with the search results, such as the total number of matching records, which helps the user navigate through the pages.

2.4 Business Value

- Improved Efficiency: Users can quickly locate specific customer records without manually scanning through long lists.
- System Performance: By using pagination, the application only loads a small portion of data at a time, keeping the interface fast and responsive.
- Data Accuracy: The system enforces strict rules on which fields can be searched, preventing errors and ensuring that search queries are always handled securely and consistently.
- Better User Experience: The combination of sorting and filtering gives users full control over how they view and interact with customer data.

BUSINESS REQUIREMENTS DOCUMENT

PUT /api/customers/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to update existing customer information and manage their associated addresses through the Lumi ERP system. It ensures that customer data remains accurate and consistent by enforcing strict validation rules before saving any changes. All updates to a customer's profile and their address list are processed as a single "all-or-nothing" operation, meaning if any part of the update fails, the entire request is rejected to prevent data errors.

1.2 Step-by-Step Flow

1. Verification: The system checks if the customer exists and belongs to the current company. If not found, the request is rejected.
2. Data Validation: The system verifies that all required fields (name, phone, store, and service tax) are provided and that the data follows specific formats (e.g., valid email, phone length of at least 6 characters, and a unique customer code).
3. Customer Update: The system updates the customer's core profile information with the new details provided.
4. Address Management: The system processes the list of addresses:

* Existing addresses are updated if changes are provided.

* New addresses are added if they are missing an ID.

* Addresses marked for removal are deleted.

5. Final Integrity Check: The system ensures that at least one address remains and that exactly one address is designated as the "main" address.
6. Completion: If all checks pass, the changes are saved permanently, and the updated customer profile is returned. If any rule is broken, the system cancels all changes to maintain data integrity.

1.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures all updates (customer details and address changes) are saved together; if one part fails, nothing is saved.
- Validation Rules: Mandatory checks that prevent incomplete or incorrect data from being saved, such as ensuring a valid email format or preventing duplicate customer codes.
- Address Lifecycle: The ability to add, update, or remove addresses in a single request, while strictly enforcing that every customer must have at least one address and exactly one "main" address.
-

Error Handling: Clear feedback provided to the user if a request is invalid (e.g., missing required fields or unauthorized access), allowing for quick corrections.

1.4 Business Value

This feature provides a reliable and efficient way to maintain customer records. By automating the validation of contact details and address management, it reduces the risk of human error and ensures that customer data is always clean and usable for business operations. The "all-or-nothing" update process guarantees that the system never ends up in a partially updated or inconsistent state, providing peace of mind for data accuracy.

2. Data

2.1 Overview

This feature allows the system to update existing customer information and manage their associated addresses through a single request. It ensures that all changes—whether updating contact details or modifying address lists—are processed together as one complete action. The system includes built-in safeguards to ensure that customer data remains accurate and that address requirements (such as always having a primary shipping address) are strictly followed.

2.2 Step-by-Step Flow

1. Verification: The system first confirms that the customer exists and belongs to the company making the request.
2. Customer Update: The system updates the customer’s core details (such as name, email, or phone number) with the provided information.
3. Address Processing: The system iterates through the provided list of addresses:

* If an address is marked for removal, it is deleted.

* If an address already exists, it is updated with the new details.

* If it is a new address, it is added to the customer's profile.

4. Business Rule Validation: The system checks that the final list of addresses meets mandatory requirements (e.g., exactly one main address exists).
5. Finalization: If all rules are met, the changes are saved permanently. If any rule is violated, the entire process is canceled to prevent data errors.

2.3 Key Concepts

–

Atomic Transaction: A "all-or-nothing" approach where the customer details and address changes are saved together; if any part of the update fails, nothing is saved.

- Address Validation: A set of mandatory rules that ensure every customer profile remains functional, specifically requiring at least one address and exactly one designated "main" shipping address.
- Address Lifecycle Management: The ability to add, update, or remove multiple addresses in a single operation based on the instructions provided in the request.
- Data Integrity: Safeguards that prevent unauthorized changes (such as modifying a customer belonging to a different company) or invalid data entries (such as missing required fields).

2.4 Business Value

This feature streamlines customer management by allowing front-end applications to synchronize a customer's entire profile in one efficient step. By enforcing strict validation rules at the database level, the system prevents "orphaned" records or incomplete customer profiles, ensuring that shipping and contact information remains reliable for downstream business operations like invoicing and logistics.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way to retrieve comprehensive details for a specific customer within the Lumi ERP system. By using a unique customer identifier, the system fetches a complete profile, including contact information, store details, tax data, and internal reporting settings. The system is designed to automatically handle different customer types—such as retail, wholesale, or franchise—ensuring the correct information is returned based on the customer's specific classification.

1.2 Step-by-Step Flow

1. Request Initiation: A request is made to retrieve a customer's profile using their unique ID.
2. Validation: The system checks that the provided ID is in the correct format and verifies that the person making the request is properly logged in.
3. Data Retrieval: The system searches the database for the customer record matching the provided ID.
4. Profile Assembly: Once found, the system gathers all relevant data, including core information, addresses, tax details, and audit logs.
5. Response:

* If successful, the system returns the full customer profile.

* If the ID is invalid, the user is not logged in, or the customer cannot be found, the system returns a specific error message explaining the issue.

1.3 Key Concepts

- Unique Identifier: A specific code assigned to every customer that ensures the system retrieves the correct record.
- Discriminator Flags: Internal markers used to categorize a customer (e.g., Retail, Wholesale, or Franchise) so the system knows how to process their specific business requirements.
- Audit Fields: A record of tracking information that shows when and how a customer profile was created or modified, ensuring data transparency.
- Error Handling: Standardized responses that inform the user if a request failed due to a bad ID, lack of permission, or a system-wide issue.

1.4 Business Value

This feature streamlines operations by providing a single, reliable source for customer data. By centralizing information like tax settings, SAP reporting values, and store details, it reduces the time staff spend manually

searching for customer records. Furthermore, the built-in security and validation checks ensure that sensitive customer data is only accessed by authorized users, maintaining the integrity and privacy of the ERP system.

2. Data

2.1 Overview

This feature provides a way to retrieve detailed information for a specific customer using their unique ID. Because our system handles different types of business relationships—specifically Retail, Wholesale, and Franchise customers—the system automatically detects the customer's type and presents the data in the format most relevant to that business model.

2.2 Step-by-Step Flow

1. Request: The system receives a request for a specific customer using their unique ID.
2. Lookup: The system searches the database for a record matching that ID. If no record is found, it returns a "Not Found" error.
3. Classification: Once the record is retrieved, the system checks internal flags to determine if the customer is a Wholesale, Franchise, or standard Retail customer.
4. Formatting: Based on the classification, the system organizes the customer's data (such as contact info, tax details, and store settings) into the specific format required for that customer type.
5. Response: The system returns the formatted customer details to the user. If any errors occur during this process (such as invalid input or server issues), the system provides the appropriate error notification.

2.3 Key Concepts

- Customer ID: A unique identifier used to locate a specific customer record in the database.
- Discriminator Flags: Internal markers (Wholesale, Franchise, or Consignment) used by the system to distinguish between different business types.
- Schema: The specific structure or "template" used to present data; this ensures that a Wholesale customer sees data relevant to their account, while a Retail customer sees their own specific set of information.
- Error Handling: Standardized responses provided by the system when a request cannot be completed, such as when a customer ID does not exist or the user is not authorized.

2.4 Business Value

This feature ensures that our API is flexible and accurate. By automatically identifying the customer type and applying the correct data format, we reduce the risk of displaying irrelevant information to users. This creates

a cleaner, more reliable experience for our partners and internal teams who rely on this data for reporting, tax compliance, and store management.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/customers/:id/status

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a simple way to update the "active" status of a customer within the Lumi ERP system. By sending a request to the system, authorized users can toggle a customer between active and inactive states. The system automatically records who performed the update and when it occurred, ensuring an accurate audit trail for customer management.

1.2 Step-by-Step Flow

1. Validation: The system checks that the request includes a valid customer identifier and a clear "active" or "inactive" status.
2. Authentication: The system verifies that the person making the request is logged in and authorized to perform updates.
3. Verification: The system searches the database to ensure the specific customer exists.
4. Update: If the customer is found, the system updates their status, logs the ID of the user who made the change, and records the current date and time.
5. Confirmation: The system returns a success message confirming the customer's ID, their new status, and the timestamp of the update.

1.3 Key Concepts

- Active Status: A true/false setting that determines if a customer is currently considered active in the system.
- Authentication: A security check to ensure only verified users can modify customer records.
- Audit Trail: The automatic recording of the user who performed the update and the exact time it happened, which is essential for tracking changes.
- Validation: A safety check to ensure the information sent to the system is in the correct format before processing begins.

1.4 Business Value

This feature improves data integrity and operational efficiency by allowing staff to quickly manage customer availability. By automating the "updated by" and "updated at" fields, the business maintains a reliable history of account changes, which is critical for reporting, compliance, and troubleshooting customer account issues.

2. Data

2.1 Overview

This feature provides a way to update the "active" status of a customer record within the Lumi ERP system. By using this tool, authorized users can toggle a customer's status (e.g., marking them as active or inactive) without needing to modify other customer details. The system automatically tracks who performed the update and when it occurred to ensure accurate record-keeping.

2.2 Step-by-Step Flow

1. Request Initiation: A user sends a request to update a specific customer, identifying them by their unique ID.
2. Validation: The system checks the request to ensure the new status is provided in the correct format (a simple true/false value).
3. Processing: If the request is valid, the system locates the customer record and updates their status, records the ID of the user who made the change, and logs the current date and time.
4. Confirmation: Once the update is saved, the system returns a confirmation containing the customer's ID, their new status, and the timestamp of the update.
5. Error Handling: If the customer cannot be found, the request is invalid, or the user lacks proper authorization, the system will return an appropriate error message instead of performing the update.

2.3 Key Concepts

- Customer Status: A simple "on/off" (boolean) setting that determines if a customer is currently active in the system.
- Audit Trail: The automatic recording of the "updater ID" and "updated at" timestamp, which provides accountability for every change made to a customer's status.
- Validation: A safety check that ensures the information sent to the system is formatted correctly before any changes are applied to the database.
- Unique Identifier: A specific code used to ensure the system updates the correct customer record every time.

2.4 Business Value

This feature streamlines customer management by allowing for quick, targeted updates to customer status. By automating the audit trail (tracking who changed what and when), the business maintains better data integrity and compliance, reducing the manual effort required to keep customer records current and accurate.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/customers

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The `POST /api/customers` feature allows the system to create a new customer record along with their associated addresses in a single operation. This process ensures that customer data is captured accurately, categorized by business type (such as wholesale or franchise), and linked to specific locations. The system automatically handles the assignment of unique identifiers and tracks which user created the record, ensuring data integrity and auditability.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in. If not, the request is rejected.
2. Request Validation: The system checks that the provided customer information (name, type, and address details) is formatted correctly.
3. Transaction Initiation: The system opens a secure "all-or-nothing" transaction. This ensures that if any part of the creation process fails, no partial or incomplete data is saved to the database.
4. Customer Creation: A new customer record is generated with a unique ID, the provided name, and the appropriate business type flags.
5. Address Processing: If addresses are provided, the system creates them and links them to the new customer. If an address is marked as the "main" address, the system updates the customer record to reflect this as the primary contact location.
6. Finalization: Once all data is successfully saved, the transaction is finalized (committed), and the system returns the newly created customer details to the user. If any error occurs during this process, the system cancels the entire operation (rollback) to keep the database clean.

1.3 Key Concepts

- Transaction: A safety mechanism that ensures multiple related database actions (like creating a customer and their addresses) either all succeed together or all fail together, preventing data inconsistencies.
- Customer Type Mapping: A logic layer that translates a simple customer category (e.g., "wholesale") into specific internal settings that the system uses to manage business rules for that customer.
- Primary Address: A designated location for a customer that the system highlights for primary contact or shipping purposes.
- Audit Tracking: The automatic recording of the user who created the record, which is essential for maintaining a history of system activity.

1.4 Business Value

This feature streamlines the onboarding of new clients by allowing users to submit comprehensive customer profiles in one go. By automating the linking of addresses and the assignment of business types, the system reduces manual data entry errors. Furthermore, the "all-or-nothing" transaction logic provides peace of mind, ensuring that the database remains accurate and reliable even if a network interruption or validation error occurs during the creation process.

2. Data

2.1 Overview

The "Create Customer" feature allows the system to register a new customer profile along with their associated addresses in a single, reliable operation. This process ensures that customer data is correctly categorized (e.g., wholesale, franchise, or consignment) and that primary contact information is linked accurately to the customer's profile.

2.2 Step-by-Step Flow

1. Initiation: The system receives a request to create a new customer, including their name, business type, and any provided addresses.
2. Customer Creation: A new customer record is generated in the database, capturing the user who initiated the request and the current timestamp.
3. Address Processing: The system iterates through the provided list of addresses, saving each one and linking it to the newly created customer.
4. Primary Address Assignment: If an address is flagged as the "main" address, the system automatically updates the customer profile to designate that specific address as the primary point of contact.
5. Finalization: If all steps succeed, the transaction is finalized (committed). If any part of the process fails, the system cancels the entire operation (rolls back) to prevent incomplete or "orphaned" data.

2.3 Key Concepts

- Atomic Transaction: A "all-or-nothing" approach where the customer and their addresses are saved together; if one part fails, nothing is saved, ensuring data consistency.
- Customer Type: A classification system that tags customers as retail, wholesale, franchise, or consignment to support specific business logic.
- Primary Address: A specific designation for a customer's main location, which is automatically linked to the customer profile for easy retrieval.
-

Audit Tracking: The system automatically records the identity of the user who created the record, providing accountability for all new entries.

2.4 Business Value

This feature streamlines the onboarding of new clients by allowing users to input comprehensive customer details—including multiple addresses—in one go. By using an atomic transaction, the business avoids data errors or partial records, ensuring that every customer profile is complete and reliable from the moment it is created. This reduces manual data entry and improves the accuracy of customer records across the ERP system.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers/new?retail=1

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides the necessary data to populate the "New Retail Customer" and "Edit Retail Customer" forms within the Lumi ERP system. When a user opens one of these pages, the system automatically retrieves all the lists required for dropdown menus (such as store locations, occupations, and tax settings) and identifies the standard default tax rate to ensure the form is ready for immediate use.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is currently logged in. If the user is not authenticated, the request is denied.
2. Data Retrieval: The system gathers all the necessary information to populate the form's dropdown menus, including available store locations, customer occupations, customer groups, and tax options.
3. Default Selection: The system identifies the specific tax configuration that should be pre-selected by default for new retail customers.
4. Form Preparation: The system bundles all the gathered lists and the default tax setting into a single package and sends it to the web page so the form can be displayed correctly.
5. Error Handling: If any part of this process fails, the system logs the issue and notifies the user that an error occurred.

1.3 Key Concepts

- Dropdown Options: The pre-defined lists (like stores or occupations) that allow users to select values from a menu rather than typing them manually, ensuring data consistency.
- Default Values: Pre-filled information that appears automatically on a form to save the user time and reduce manual data entry.
- Authentication: The security process that ensures only authorized users can access or modify customer records.
- Retail Context: A specific configuration setting that ensures the form displays only the options and rules relevant to retail customers, keeping the interface clean and relevant.

1.4 Business Value

This feature streamlines the customer onboarding and management process by automating the setup of retail forms. By providing pre-populated dropdowns and automatic defaults, it reduces the time staff spend on manual data entry, minimizes the risk of human error, and ensures that every new retail customer is categorized and taxed correctly from the moment they are added to the system.

2. Data

2.1 Overview

This feature provides the necessary data to populate the "New Retail Customer" and "Edit Retail Customer" forms in the Lumi ERP system. When a user opens one of these pages, the system automatically fetches the required default settings and the complete lists of options for all dropdown menus, ensuring the form is ready for immediate use.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is currently logged in. If not, the request is denied.
2. Data Retrieval: The system gathers all necessary information from the database, including available stores, sales staff, occupations, wholesale customer associations, customer groups, and tax options.
3. Setting Defaults: The system automatically selects the user's current store as the default location and identifies the primary "Always Use" tax rate to pre-fill the form.
4. Response Construction: The system packages the default values and the full lists of dropdown options into a single response, which is then sent to the user's browser.
5. Error Handling: If any part of the process fails unexpectedly, the system returns a standard error message to prevent the application from crashing.

2.3 Key Concepts

- Default Values: Pre-selected information (such as the user's store or standard tax rate) that saves the user time by reducing manual data entry.
- Dropdown Options: The complete lists of choices (e.g., list of salespersons or customer groups) that the system fetches to ensure the user always sees the most up-to-date information.
- Contextual Scoping: The system ensures that all data retrieved is relevant specifically to the user's company, preventing cross-contamination of data between different business entities.

2.4 Business Value

This feature streamlines the customer onboarding process by automating form preparation. By pre-filling common fields and providing accurate, real-time dropdown options, it reduces manual effort for staff, minimizes data entry errors, and ensures that new retail customers are categorized and taxed correctly from the moment they are added to the system.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers/new?wholesale=1

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides the necessary data to initialize the "New Wholesale Customer" form in the Lumi ERP system. When a user navigates to the page to add a new wholesale customer, this process automatically prepares the form by pre-filling standard information and populating all necessary selection menus (dropdowns) with the most current data from the system.

1.2 Step-by-Step Flow

1. Initialization: When the "Add Wholesale Customer" page loads, the system requests the required form data.
2. Setting Defaults: The system automatically applies standard settings for a new wholesale customer, such as setting the customer type to "wholesale," enabling the account, defaulting the currency to IDR, and setting initial credit and tax configurations to zero or their standard enabled states.
3. Gathering Options: The system retrieves the latest lists from the database to populate the form's dropdown menus, including customer groups, available salespersons, currencies, pricelists, tax options, accounts, and countries.
4. Form Delivery: The system combines the default values and the dropdown options into a single package and sends them to the browser so the form can be displayed to the user.
5. Error Handling: If the user is not logged in or if a system error occurs during this process, the system will return an appropriate error message instead of the form data.

1.3 Key Concepts

- Form Bootstrap: The process of preparing and loading all the data required to display a form immediately upon opening a page.
- Default Values: Pre-filled information that saves the user time by automatically setting common fields to standard wholesale business settings.
- Master Data: The central, authoritative lists (such as countries, currencies, or salespersons) that the system uses to ensure consistency across all forms.
- Dropdown Options: The selectable lists provided to the user to ensure they choose valid, system-recognized entries for fields like "Salesperson" or "Customer Group."

1.4 Business Value

This feature streamlines the workflow for sales and administrative staff by automating the setup of new wholesale accounts. By pre-filling standard wholesale settings and providing accurate, up-to-date selection lists, the system

reduces manual data entry, minimizes the risk of human error, and ensures that all new wholesale customers are configured consistently according to company policy from the moment they are created.

2. Data

2.1 Overview

This feature provides the necessary data to initialize the "New Wholesale Customer" form in the Lumi ERP system. When a user navigates to the page to add a new wholesale customer, the system automatically fetches a "bootstrap" package. This package contains two things: the standard default settings for a new wholesale account and the complete lists of options (such as currencies, tax rates, and sales groups) required to populate the form's dropdown menus.

2.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and authorized to access the page.
2. Request Validation: The system confirms that the request is specifically for a "wholesale" customer type.
3. Data Gathering: The system retrieves the default configuration values (such as default currency and credit limits) and gathers all necessary master data (such as lists of available salespersons, tax rates, and account codes).
4. Form Preparation: The system bundles the default values and the dropdown options into a single response.
5. Delivery: The prepared data is sent to the user's browser to instantly populate the form, ensuring a smooth and consistent data entry experience.

2.3 Key Concepts

- Bootstrap Data: A collection of default values and reference lists sent to the browser at once so the form is ready for use immediately upon loading.
- Master Data: The official, centralized lists of information (like currencies, tax rates, or user accounts) that ensure consistency across the entire ERP system.
- Default Values: Pre-filled settings for a new customer record that reduce manual data entry and ensure that new wholesale accounts follow company standards from the start.
- Dropdown Options: The selectable lists provided to the user to ensure they choose from valid, pre-approved categories (e.g., selecting a specific tax rate rather than typing one in).

2.4 Business Value

- Efficiency: By pre-filling the form with standard wholesale defaults, users spend less time manually entering repetitive information.
- Data Accuracy: Using standardized dropdown lists for taxes, currencies, and accounts prevents manual entry errors and ensures that all customer records are consistent.
- Improved User Experience: The "bootstrap" approach ensures the form loads with all necessary information ready to go, preventing delays or the need for multiple separate requests to the server.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers/:id/returns

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of all product returns associated with a specific retail customer. By using a unique customer identifier, the system fetches the history of returned items, including the date of the return, the amount involved, and the current status of the request. This data is specifically designed to populate the "Customer Purchase Returns" table within the customer details view of the Lumi ERP system.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided customer identifier is formatted correctly. If the format is invalid, the request is rejected.
2. Customer Verification: The system searches for the customer in the database. It then confirms that the customer is classified as a "Retail" customer. If the customer cannot be found, or if they are classified as wholesale, franchise, or consignment, the system will not return any data.
3. Data Retrieval: Once the customer is verified as a retail account, the system gathers all recorded return transactions linked to that specific customer.
4. Response: The system delivers the list of return records to the user. If any errors occur during this process (such as authentication issues or server errors), the system provides an appropriate error message.

1.3 Key Concepts

- Retail Customer: A specific account type within the ERP. This feature is restricted to these customers and excludes wholesale, franchise, or consignment accounts.
- Return Record: A digital entry representing a product return, containing details such as the date, the monetary value, and the current processing status.
- Path Parameter: A specific piece of information (the customer ID) included in the web address that tells the system exactly which customer's data to retrieve.

1.4 Business Value

This feature improves operational efficiency by allowing staff to quickly view a customer's return history directly within the ERP interface. By automating the retrieval of this data, support teams can resolve customer inquiries faster and maintain accurate records of product returns, ensuring a smoother experience for retail customers.

2. Data

2.1 Overview

This feature provides a way to retrieve a list of purchase returns for a specific retail customer. It is designed to power the "Customer Purchase Returns" table within the Lumi ERP system. The system ensures that this data is only accessible for customers classified as "Retail," automatically excluding wholesale, franchise, or consignment accounts.

2.2 Step-by-Step Flow

1. Request Validation: The system receives a request for a specific customer's returns. It first checks that the provided customer identifier is formatted correctly.
2. Customer Verification: The system looks up the customer in the database. If the customer does not exist, or if they are flagged as wholesale, franchise, or consignment, the system denies the request.
3. Data Retrieval: If the customer is confirmed as a retail customer, the system fetches all associated return records from the database, organized by the most recent date first.
4. Response: The system returns the list of return records to the user, including a count of the total items found. If any errors occur during the process (such as an invalid ID or a non-retail customer), the system provides an appropriate error message.

2.3 Key Concepts

- Retail Customer: A standard customer account that does not fall under wholesale, franchise, or consignment categories. This feature is restricted to this specific group.
- Return Record: A historical log of a purchase return, including the date, the amount returned, and the current status of that return.
- Identifier Validation: A security and quality check to ensure the request is asking for a valid, properly formatted customer record before attempting to search the database.

2.4 Business Value

This feature improves operational efficiency by providing customer service and support teams with immediate, accurate visibility into a retail customer's return history. By enforcing strict business rules regarding customer types, the system ensures that data is surfaced only for the appropriate audience, maintaining data integrity and supporting the specific workflows required for retail account management.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/customers/:id/sales

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to view the complete purchase history for a specific retail customer within the Lumi ERP system. By selecting a customer, authorized users can retrieve a detailed list of items purchased, including the transaction amount and the date of each purchase, presented in chronological order.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the person requesting the information is logged in and has the necessary permissions to view customer sales data.
2. Customer Verification: The system checks the database to ensure the requested customer exists. If the customer cannot be found, the system returns an error.
3. Data Retrieval: Once the customer is confirmed, the system gathers all sales records linked to that specific customer.
4. Display: The system presents the list of purchases, showing the item name, the amount spent, and the date of the transaction.

1.3 Key Concepts

- Authentication: The process of confirming the identity of the user to ensure they are allowed to access the system.
- Authorization: The process of checking if a verified user has the specific permission required to view sensitive sales records.
- Customer ID: A unique identifier used by the system to ensure the correct customer's data is retrieved.
- Sales Record: A stored entry containing details about a specific transaction, such as what was bought, how much it cost, and when it happened.

1.4 Business Value

This feature empowers staff to provide better customer service by offering immediate access to a customer's buying habits and history. By having this information readily available, the team can more effectively manage customer relationships, resolve inquiries regarding past orders, and identify opportunities for personalized recommendations or support.

2. DATA

2.1 Overview

This feature provides a way to retrieve a detailed history of purchases for a specific retail customer within the Lumi ERP system. By providing a unique customer identifier, the system will return the customer's name alongside a chronological list of all items they have purchased, making it easy to view their buying activity.

2.2 Step-by-Step Flow

1. Verification: The system receives a request for a specific customer's sales history. It first checks the database to ensure the customer exists. If the customer cannot be found, the system stops and reports that the customer does not exist.
2. Data Retrieval: Once the customer is confirmed, the system searches the sales records for all transactions linked to that specific customer.
3. Sorting: The system organizes the retrieved sales records, ensuring the most recent purchases appear first.
4. Response: The system compiles the customer's name and their sorted list of purchases into a single report and delivers it to the user.

2.3 Key Concepts

- Customer Identifier: A unique code used to ensure the system retrieves data for the correct person.
- Sales Records: A collection of transaction details, including the item name, the cost, and the date the purchase was made.
- Chronological Sorting: The process of arranging the purchase history so that the newest transactions are displayed at the top of the list.
- Validation: A safety check performed at the start of the process to confirm that the requested customer is valid before attempting to pull their data.

2.4 Business Value

This feature improves customer service and sales visibility by allowing staff to quickly access a customer's purchase history. By providing an organized, up-to-date view of what a customer has bought, the business can better understand customer preferences, resolve inquiries faster, and provide a more personalized shopping experience.

BUSINESS REQUIREMENTS DOCUMENT

Customer Vehicles Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Customer Vehicles feature allows the system to store, manage, and display detailed information about vehicles associated with a specific customer. This includes support for various vehicle types—such as cars, motorcycles, and heavy equipment—ensuring that service teams have the right technical data at their fingertips to provide accurate support and maintenance.

1.2 Step-by-Step Flow

1. Form Setup: When a user opens the "Add Vehicle" form, the system automatically retrieves a list of available vehicle makes and models. This ensures the user can select from standardized options, keeping the data clean and consistent.
2. Data Entry: The user fills out the vehicle details. The form is dynamic: if "heavy equipment" is selected, additional fields (such as hour-meter readings and engine specifications) appear, while these are hidden for standard cars or motorcycles.
3. Submission: Once the user submits the form, the system saves the vehicle record, automatically linking it to the current customer and the user's store location.
4. Display: The system provides a paginated list of all vehicles linked to a specific customer. This list automatically translates internal codes into readable names (e.g., showing "Toyota" instead of a complex ID), making it easy for staff to identify the correct vehicle at a glance.

1.3 Key Concepts

- Vehicle Metadata: The standardized list of makes and models used to populate dropdown menus, ensuring users don't have to type this information manually.
- Dynamic Form Logic: A feature that adjusts the input fields based on the type of vehicle selected, ensuring that only relevant information (like engine power for heavy machinery) is collected.
- Data Normalization: The process of linking vehicle records to specific customers and stores, which allows for accurate reporting and service history tracking.
- Pagination: A method of displaying large lists of vehicles in smaller, manageable chunks to keep the interface fast and easy to navigate.

1.4 Business Value

- Improved Data Accuracy: By using standardized dropdowns for makes and models, we eliminate typos and inconsistent naming conventions.
- Operational Efficiency: Service staff can quickly access a customer's entire fleet history, reducing the time spent searching for vehicle details during service appointments.

- Tailored Maintenance: Because the system captures specific technical details (like engine specs or hour meters for heavy equipment), service teams can provide more precise maintenance recommendations and parts ordering.
- Scalability: The system is designed to handle large volumes of vehicle data per customer, ensuring that as our customer base grows, the platform remains performant and organized.

BUSINESS REQUIREMENTS DOCUMENT

Customer Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Customer Schema feature provides a structured way to manage customer information within the Lumi ERP system. It allows the business to categorize customers into specific types (Retail, Wholesale, Franchise, or Consignment), maintain detailed contact and tax information, and track their purchase history. This feature ensures that customer data is organized, searchable, and easily updatable, supporting better operational oversight.

1.2 Step-by-Step Flow

1. Customer Creation: When a new customer is added, the system captures essential details (such as name, store, and company) and assigns a "type." The system automatically sets the customer as "active" and records the creation timestamp and the user who performed the action.
2. Categorization: Based on the selected type, the system applies specific internal flags (Wholesale, Franchise, or Consignment) to ensure the customer is correctly classified for reporting and business logic.
3. Data Management & Retrieval: Users can view a list of customers. This list is dynamic, allowing for filtering by criteria such as name, region, phone number, or status. The system also supports sorting to help users find specific records quickly.
4. Status Updates: If a customer's status changes (e.g., deactivating a customer), the system updates the record and logs the change, including the timestamp and the user responsible for the update.
5. Purchase History: The system allows users to view the purchase history for any specific customer, providing visibility into their transaction status, amounts, and associated documents.

1.3 Key Concepts

- Customer Type: A classification system that distinguishes between Retail, Wholesale, Franchise, and Consignment customers to apply the correct business rules.
- Active Status: A toggle that determines if a customer is currently enabled in the system; this can be updated at any time.
- Filtering & Sorting: Tools that allow users to narrow down large lists of customers or purchase records based on specific fields like name, code, or date.
- Audit Tracking: The system automatically records who created or updated a customer record and when, ensuring data accountability.
- Purchase History: A dedicated view for each customer that lists their past transactions, including status (e.g., Draft or Completed) and financial amounts.

1.4 Business Value

-

Operational Efficiency: By centralizing customer data and providing robust search and filter capabilities, staff can quickly access the information they need to serve customers.

- Data Accuracy: Standardized schemas ensure that all customer records contain consistent information, reducing errors in reporting and communication.
- Improved Decision Making: The ability to categorize customers and view their purchase history allows the business to better understand customer behavior and tailor sales strategies accordingly.
- Accountability: Automated tracking of record creation and status changes provides a clear audit trail, which is essential for maintaining data integrity in an ERP environment.

BUSINESS REQUIREMENTS DOCUMENT

Detail Customer Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a structured way to retrieve detailed information for a specific customer within the Lumi ERP system. Because the system handles different types of business relationships, the feature intelligently identifies and fetches the correct data based on whether the customer is classified as a Retail, Wholesale, or Franchise partner. This ensures that the information returned is relevant to that specific customer type.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view the details of a customer using a unique identifier.
2. Type Identification: The system checks the customer's classification (Retail, Wholesale, or Franchise) to determine which data set to retrieve.
3. Data Retrieval:

* For Retail Customers, the system gathers core profile data, links to their assigned store and customer group, and pulls their associated addresses.
* For Wholesale Customers, the system gathers core profile data, store and group information, and associated addresses.
* For Franchise Customers, the system gathers more extensive data, including specific contact details, financial account settings, and administrative information (such as who created or last updated the record).

4. Data Assembly: The system combines the customer's primary record with related information (like addresses and group names) into a single, organized response.
5. Response Delivery: The system returns the complete customer profile to the user.

1.3 Key Concepts

- Customer Classification: A method of categorizing customers (Retail, Wholesale, or Franchise) to ensure the system displays the correct fields and business logic for each.
- Data Linking: The process of automatically pulling in related information—such as store names, occupation details, or user names—so the customer profile is complete and easy to read.
- Address Aggregation: A feature that collects all addresses associated with a customer and presents them as a single, organized list within the customer's profile.
- Unique Identifier: A specific code used to ensure the system retrieves the exact customer record requested without confusion.

1.4 Business Value

-

Improved Data Accuracy: By using specific schemas for different customer types, the system ensures that users only see relevant, accurate information, reducing confusion.

- Operational Efficiency: Staff can quickly access a comprehensive view of a customer—including their contact details, financial settings, and history—without needing to look up information in multiple places.
- Better Relationship Management: Having a clear, detailed view of a customer's profile (especially for complex accounts like franchises) allows for more informed decision-making and better service delivery.

BUSINESS REQUIREMENTS DOCUMENT

Edit Customer Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Edit Customer" feature allows users to update the details of a retail customer, including their personal information and associated addresses. The system is designed to ensure that all changes are processed reliably and that the customer's data remains consistent and accurate, such as ensuring every customer has exactly one designated "main" address.

1.2 Step-by-Step Flow

1. Validation: The system checks that the required information (name, phone, store, and tax ID) is provided and that the data meets specific quality standards (e.g., phone number length).
2. Customer Update: The main customer profile is updated with the new information provided in the request.
3. Address Management: The system processes the list of addresses:

* Existing addresses are updated if changes are provided.

* New addresses are added to the customer's profile.

* Addresses marked for deletion are removed.

4. Integrity Check: The system verifies that the customer still has exactly one "main" address. If this rule is violated, the entire update is canceled to prevent data errors.
5. Synchronization: The system automatically copies the "main" address details to the customer's primary profile record to ensure consistency across the system.
6. Confirmation: Once the changes are saved, the system returns the updated customer profile so the screen can refresh immediately with the latest information.

1.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures all changes (customer profile and addresses) are saved together. If any part of the update fails, the entire process is canceled, leaving the data exactly as it was before.
- Main Address: A mandatory designation for one specific address in a customer's profile. The system enforces that every customer must have exactly one, ensuring reliable contact and shipping information.
- Data Integrity: The practice of maintaining accurate and consistent data by enforcing rules (like the "one main address" requirement) during every update.
- Retail Customer: The specific category of customer this feature manages, ensuring that wholesale, franchise, or consignment settings are not accidentally modified through this interface.

1.4 Business Value

This feature provides a streamlined and error-proof way to maintain customer records. By automating the validation of addresses and ensuring that critical information is always synchronized, the system reduces manual data entry errors and ensures that customer contact information is always reliable for sales and shipping operations.

BUSINESS REQUIREMENTS DOCUMENT

Create Customer Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Create Customer" feature allows the system to register a new customer record along with their associated addresses in a single, unified action. This process is designed to be "atomic," meaning that the customer and their addresses are saved together as one complete unit. If any part of the process fails, the system ensures that no partial or incomplete data is saved, keeping your database clean and reliable.

1.2 Step-by-Step Flow

1. Receive Request: The system accepts a request containing the customer's core details (such as name, store, and company) and an optional list of addresses.
2. Categorize Customer: The system automatically identifies the customer type (Retail, Wholesale, Franchise, or Consignment) and sets the appropriate internal flags to ensure they are categorized correctly in the system.
3. Create Customer Record: A new customer profile is created in the database. The system automatically assigns a unique ID, sets the status to "active," and records the user who created the entry.
4. Add Addresses: If addresses are provided, the system links each one to the newly created customer.
5. Set Primary Address: If one of the provided addresses is marked as the "main address," the system automatically updates the customer's main profile record with that specific address information.
6. Finalize: Once all steps are successfully completed, the system confirms the creation and returns the full customer record.

1.3 Key Concepts

- Atomic Transaction: A safety feature that ensures all parts of the creation process (customer profile + addresses) succeed together. If one part fails, the entire operation is canceled to prevent data errors.
- Discriminator Flags: Internal settings that classify a customer (e.g., Wholesale vs. Retail) based on the type provided, allowing the system to apply the correct business rules to that customer.
- Main Address: A specific designation for an address that the system uses to populate the primary contact location on the main customer profile.

1.4 Business Value

- Data Integrity: By using an atomic process, you avoid "orphan" records where a customer might be created without their necessary address information, or vice versa.
- Efficiency: Users can input a customer and all their relevant locations in one go, reducing the time spent on manual data entry.
- Consistency: Automated categorization and address handling ensure that customer data is standardized across the entire ERP, making reporting and operations more reliable.

BUSINESS REQUIREMENTS DOCUMENT

Customer Return Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Customer Return feature allows the system to track and display product returns specifically for retail customers. It ensures that return records are accurately linked to the correct customer, store, and user, while providing a detailed breakdown of the items returned. The system includes built-in validation to ensure that these return records are only associated with standard retail customers, excluding wholesale, franchise, or consignment accounts.

1.2 Step-by-Step Flow

1. Customer Validation: When a request is made to view returns, the system first checks the customer's profile to confirm they are a retail customer (i.e., not wholesale, franchise, or consignment).
2. List Retrieval: If the customer is a valid retail customer, the system fetches a list of all their previous returns, including key details like the document number, date, status, total amount, and the store where the return occurred.
3. Detailed View Request: When a specific return is selected, the system retrieves the full details of that transaction.
4. Data Aggregation: The system gathers information from multiple sources to build the full view, including:

* The return header (date, status, reason, and total amount).

* The specific items returned (including product names, quantities, and prices).

* Supporting information such as the vehicle involved (if applicable), the store name, and the names of the users who created or updated the record.

5. Display: The compiled information is presented to the user, showing a clear history of the return transaction and its individual line items.

1.3 Key Concepts

- Retail Customer: A standard customer account that is not classified as wholesale, franchise, or consignment.
- Return Header: The top-level information for a return, such as the document number, date, and overall status.
- Return Items: The individual products included in a single return, each with its own quantity, price, and reason for return.
- Data Validation: A security and accuracy check that ensures only appropriate customer types can access or be associated with the retail return process.

1.4 Business Value

-

Improved Accuracy: By automatically validating customer types, the system prevents data entry errors and ensures that return reporting remains clean and specific to retail operations.

- Enhanced Visibility: Staff can quickly access a comprehensive history of a customer's returns, including specific product details, which helps in resolving customer service inquiries faster.
- Operational Efficiency: By linking returns to specific stores and users, the business can better track return trends and staff performance, leading to more informed decision-making regarding inventory and customer satisfaction.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/vehicles

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The `GET /api/vehicles` feature provides a flexible way for users to retrieve a list of vehicles from the system. It is designed to handle large datasets by allowing users to narrow down results using specific filters, date ranges, and a general search function. The system also supports custom sorting to ensure the most relevant information appears first.

1.2 Step-by-Step Flow

1. Validation: The system checks the incoming request to ensure that any provided filters (such as vehicle type or date categories) use valid, supported values. If the input is invalid, the request is rejected.
2. Initialization: The system prepares to pull the full list of vehicles from the database.
3. Filtering: The system applies specific criteria provided by the user, such as matching a specific registration number, customer name, or store location.
4. Date Range Application: If a date range is requested, the system narrows the results to vehicles created or registered within the specified "from" and "to" dates.
5. General Search: If a general search term is provided, the system scans across registration numbers, hull numbers, VINs, and customer names to find partial matches.
6. Sorting: The system organizes the final list based on the user's preferred field (e.g., customer name) and order (ascending or descending). If no preference is given, it defaults to showing the most recently created vehicles first.
7. Execution: The system retrieves the filtered, sorted list and returns it to the user.

1.3 Key Concepts

- Filtering: The ability to narrow down the vehicle list by specific attributes like vehicle type, store ID, or unique identifiers (VIN/FIN).
- Date Range Filtering: A feature that allows users to focus on vehicles based on their creation date or registration date within a specific timeframe.
- General Search: A "fuzzy" search capability that looks for a keyword across multiple fields simultaneously to help users find vehicles without knowing the exact identifier.
- Sorting: The process of arranging the output list in a specific order to improve readability and data management.
- Validation: A safety check that ensures the system only processes requests with recognized parameters, preventing errors and ensuring data integrity.

1.4 Business Value

This feature empowers staff to manage fleet inventory efficiently by providing quick access to specific vehicle records. By offering robust search and filter capabilities, users can spend less time navigating through long lists and more time managing operations. The ability to sort and filter by date or customer also supports better reporting and auditing, ensuring that the right vehicle information is always available when needed.

2. Data

2.1 Overview

The Vehicle API provides a flexible way to retrieve a list of vehicles from the Lumi ERP system. It is designed to help users quickly find specific vehicles or groups of vehicles by allowing them to filter, search, and sort the data based on various criteria such as registration details, customer information, or specific timeframes.

2.2 Step-by-Step Flow

1. Initialization: The system starts by accessing the complete list of vehicles stored in the database.
2. Type Filtering: If a specific vehicle type (e.g., Car, Motorcycle, or Heavy Equipment) is requested, the system narrows the list to only include that category.
3. Specific Filtering: The system applies any provided exact matches, such as a specific registration number, VIN, or store location.
4. Date Range Filtering: If a date range is provided, the system filters the results based on either the registration date or the creation date, depending on the user's preference.
5. General Search: If a general search term is entered, the system scans across key fields (like registration number, VIN, or customer name) to find partial matches.
6. Sorting: Finally, the system organizes the resulting list based on the user's preferred field and order (ascending or descending). If no preference is provided, it defaults to showing the most recently created vehicles first.

2.3 Key Concepts

- Filtering: The ability to narrow down a large list of vehicles to a smaller, more relevant subset based on specific attributes.
- Date Range: A feature that allows users to isolate records created or registered within a specific window of time.
- General Search: A broad search function that looks for keywords across multiple descriptive fields simultaneously.

– Sorting: The process of arranging the final list in a specific order (e.g., alphabetical by customer or chronological by date) to make the data easier to read.

2.4 Business Value

This feature empowers users to manage their fleet efficiently by reducing the time spent searching for specific assets. By providing robust filtering and sorting capabilities, the system ensures that staff can quickly access the exact vehicle information they need—whether they are looking for a single unit by its VIN or generating a report of all vehicles registered at a specific store within a certain month.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/vehicles

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to add a new vehicle record to the Lumi ERP system. By providing specific vehicle details—such as the make, model, year, and VIN—and linking it to an existing customer, the system creates a permanent record that tracks ownership and vehicle history.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the person making the request is currently logged in.
2. Validation: The system checks that all required vehicle information (customer ID, make, model, year, and VIN) has been provided.
3. Customer Verification: The system confirms that the customer ID provided actually exists in the database.
4. Record Preparation: The system generates a unique ID for the vehicle, assigns the current user as the creator, and stamps the record with the current date and time.
5. Data Storage: The new vehicle information is saved into the system database.
6. Confirmation: The system returns the complete, newly created vehicle record to confirm the process was successful.

1.3 Key Concepts

- Customer ID: A unique identifier used to ensure the vehicle is correctly linked to the right customer account.
- VIN (Vehicle Identification Number): The unique code used to identify a specific vehicle.
- Authentication: The security process that ensures only logged-in, authorized users can add new data to the system.
- Validation: A safety check to ensure that all necessary information is present and correct before the system attempts to save it.

1.4 Business Value

This feature streamlines the vehicle management process within the Lumi ERP. By automating the creation of vehicle records and ensuring they are strictly linked to verified customers, the system reduces manual data entry errors and maintains high data integrity. This provides a reliable foundation for tracking customer assets and managing service history effectively.

2. Data

2.1 Overview

The "Create Vehicle" feature allows users to add a new vehicle record to the Lumi ERP system. This process ensures that every vehicle is correctly linked to an existing customer and tracks essential details such as the make, model, year, and unique vehicle identification number (VIN). The system automatically handles administrative tasks like assigning a unique ID, recording who created the entry, and logging the exact time of creation.

2.2 Step-by-Step Flow

1. Request Submission: The user submits a request containing the vehicle details (make, model, year, VIN) and the ID of the customer to whom the vehicle belongs.
2. Authentication Check: The system verifies that the user is currently signed in and authorized to perform this action.
3. Customer Validation: The system checks the database to ensure the provided customer ID exists. If the customer cannot be found, the process stops and returns an error.
4. Data Preparation: The system generates a unique identifier for the new vehicle and captures the current date and time.
5. Record Creation: The system saves the vehicle information into the database, linking it to the specified customer and marking the current user as the creator.
6. Confirmation: Upon successful saving, the system returns a confirmation message along with the details of the newly created vehicle record.

2.3 Key Concepts

- Customer Binding: The requirement that a vehicle must be associated with a valid, pre-existing customer record in the system.
- Unique Identifier: A system-generated, one-of-a-kind code used to distinguish each vehicle record from all others.
- VIN (Vehicle Identification Number): A unique code used to identify the specific vehicle; the system ensures no two vehicles share the same VIN.
- Audit Trail: The automatic recording of "who" created the record and "when" it was created/updated, ensuring data accountability.

2.4 Business Value

This feature streamlines the vehicle management process within the Lumi ERP by automating data entry and ensuring data integrity. By validating customer associations and enforcing unique identifiers like the VIN, the system prevents duplicate entries and orphaned records. This provides a reliable, organized foundation for tracking customer assets, which is essential for accurate reporting and efficient service management.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/vehicles/new

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides the necessary information to populate the "Add New Vehicle" form in the Lumi ERP system. When a user navigates to the page to add a vehicle, this tool automatically retrieves the current list of available vehicle makes and models, ensuring that the dropdown menus are always up-to-date and accurate.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to access the vehicle data.
2. Data Retrieval: The system gathers all currently "active" vehicle makes from the database.
3. Model Association: The system gathers all currently "active" vehicle models from the database.
4. Data Delivery: The system combines these lists and sends them to the "Add Vehicle" form so the user can select the appropriate make and model from the dropdown menus.
5. Error Handling: If the user is not logged in, or if a technical issue occurs during the process, the system provides a clear error message to prevent the form from loading with incorrect or missing data.

1.3 Key Concepts

- Active Records: The system only retrieves makes and models that are currently marked as "active," ensuring users cannot select outdated or discontinued options.
- Reference Data: This refers to the foundational lists (makes and models) that act as the building blocks for the vehicle entry form.
- Authentication: A security step that ensures only verified users can access the vehicle database.

1.4 Business Value

- Data Integrity: By only displaying "active" makes and models, the system prevents users from accidentally entering invalid vehicle information.
- Improved User Experience: Automating the population of dropdown menus saves time and reduces manual data entry errors for staff.
- System Reliability: Standardized error handling ensures that if the system encounters a problem, it fails gracefully and notifies the user rather than displaying broken or incomplete forms.

2. Data

2.1 Overview

This feature provides the necessary information to populate the "Add New Vehicle" form in the Lumi ERP system. When a user navigates to the page to add a vehicle, this tool automatically gathers the current list of available vehicle manufacturers (makes) and their corresponding models. By ensuring the system only displays "active" options, we keep the user interface clean and prevent users from selecting outdated or discontinued vehicle data.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to access the system. If not, the request is denied.
2. Data Retrieval: The system fetches the list of all currently active vehicle makes from the database.
3. Model Retrieval: The system fetches the list of all currently active vehicle models associated with those makes.
4. Data Compilation: The system combines the lists of makes and models into a single, organized package.
5. Delivery: The compiled information is sent to the user's screen to populate the dropdown menus on the "Add Vehicle" form.

2.3 Key Concepts

- Active Status: A filter applied to ensure that only currently supported or relevant vehicle makes and models are shown to the user.
- Metadata: The background information (names and IDs of vehicles) required to make a form functional, rather than the actual vehicle records themselves.
- Dropdown Population: The process of filling the selection menus on the user interface so that users can choose from a pre-defined list rather than typing information manually.

2.4 Business Value

- Data Accuracy: By automatically filtering for "active" items, we reduce the risk of users selecting obsolete vehicle data, which improves the quality of the information stored in the ERP.
- Improved User Experience: Providing a pre-populated list of makes and models makes the "Add Vehicle" process faster and less prone to human error compared to manual entry.
- System Efficiency: This feature centralizes the retrieval of form data, ensuring that the application remains responsive and consistent across the entire platform.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Internal List page provides a centralized view for managing internal purchase orders. This feature allows users to browse, search, and sort through all internal franchise orders, making it easier to track the status of goods moving between warehouses and stores.

1.2 Step-by-Step Flow

1. Initial Load: When the page is first opened, the system automatically retrieves and displays a list of all internal purchase orders.
2. Filtering: Users can narrow down the list by entering specific criteria into the filter bar, such as the Document Number, date ranges, store or warehouse location, order status, or source.
3. Searching: After entering filter criteria, clicking the "Search" button refreshes the table to show only the matching records. This action resets the view to the first page of results.
4. Sorting: Users can click on column headers (such as Document Number, Date, Store, or Status) to organize the list. Clicking once sorts the data in ascending order; clicking again toggles it to descending order.
5. Navigation: If there are many orders, users can move through the list using the pagination controls at the bottom of the page.
6. Viewing Details: Users can click on any row in the table to be redirected to a dedicated page containing the full details of that specific purchase order.

1.3 Key Concepts

- Internal Purchase Order: A specific type of order used for tracking inventory movement within the franchise network (e.g., from a central warehouse to a specific store).
- Filter Bar: A set of input fields and dropdowns that allow users to refine the list based on specific business data.
- Status Badge: A visual indicator on each row that clearly displays the current state of an order (e.g., "Ordered" or "Received").
- Pagination: A method of breaking a large list of records into smaller, manageable pages (20 items per page) to improve performance and readability.
- Sortable Columns: Table headers that allow users to reorder the list based on specific data points, such as dates or document numbers.

1.4 Business Value

This feature improves operational efficiency by providing inventory managers with a clear, searchable, and organized view of internal supply chain activity. By enabling quick access to specific order statuses and details, the team can reduce time spent searching for information, resolve discrepancies faster, and maintain better oversight of inventory distribution across the franchise.

2. Logic

2.1 Overview

The Franchise Purchase Order Internal List page provides a centralized view for managing and tracking purchase orders across your franchise network. This feature allows users to browse all internal purchase orders, apply specific filters, sort the data, and navigate through pages of records to find exactly what they need.

2.2 Step-by-Step Flow

1. Request Data: The system retrieves a list of purchase orders based on the filters, sorting preferences, and page number you have selected in the interface.
2. Process Records: Each purchase order record is retrieved and prepared for display.
3. Format Information: The system converts raw data into a user-friendly format, including:

* Formatting dates for readability.
* Converting numerical values into currency format.
* Assigning color-coded status badges to indicate the current progress of the order.

4. Display: The processed information is presented in a clean table, replacing any previous results with the updated list.

2.3 Key Concepts

– Filters: Tools that allow you to narrow down the list of purchase orders by specific criteria (such as store, supplier, or date range).
– Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
– Status Badges: Visual indicators that show the current state of an order (e.g., "Ordered" or "Partially Received") to help you quickly identify which orders require attention.
– Sorting: The ability to reorder the list based on specific columns, such as date or document number, to help you prioritize your work.

2.4 Business Value

This feature improves operational efficiency by providing a clear, organized view of all franchise purchase orders. By enabling quick searching and filtering, staff can spend less time hunting for documents and more time managing inventory. The standardized status badges and currency formatting ensure that team members can quickly assess the financial and logistical status of any order at a glance, reducing errors and improving communication between the warehouse, suppliers, and stores.

3. Data

3.1 Overview

The Franchise Purchase Order Internal List page provides a centralized dashboard for viewing and managing all purchase orders created by franchises. This feature allows users to easily browse through orders, apply specific filters to narrow down results, and view key details such as order status, financial amounts, and associated store or supplier information in a clean, organized table format.

3.2 Step-by-Step Flow

1. Requesting Data: When you open the page or apply filters (such as searching by store, supplier, or date range), the system sends a request to retrieve the relevant list of purchase orders.
2. Sorting and Pagination: The system organizes the orders based on your chosen sorting preferences and breaks the list into manageable pages to ensure the interface remains fast and easy to navigate.
3. Data Transformation: The system takes the raw order information and converts it into a user-friendly format, ensuring that dates, currency values, and status labels are displayed clearly.
4. Displaying Results: The formatted data is populated into the table, replacing any previous results with the updated list based on your current search or filter criteria.

3.3 Key Concepts

- Filters: Tools that allow you to narrow down the list of orders by specific criteria like store name, supplier, or date, helping you find exactly what you need.
- Pagination: A method of dividing a large list of orders into smaller pages, which improves performance and makes the list easier to read.
- Workflow Status: A clear label (such as "Ordered" or "Received Partial") that indicates the current stage of a purchase order in the supply chain.
- Currency Formatting: The automatic conversion of raw numerical values into a standard monetary format (e.g., $1,000.00) for better readability.

3.4 Business Value

This feature improves operational efficiency by providing a "single source of truth" for franchise inventory procurement. By enabling quick searching and filtering, staff can spend less time hunting for documents and more time managing inventory. The clear status tracking and standardized financial display reduce the risk of errors, ensuring that store managers and warehouse staff are always aligned on the progress of their orders.

BUSINESS REQUIREMENTS DOCUMENT

Store - Stock Returns List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Return List page is a centralized dashboard within the Lumi ERP system that allows users to view, filter, and manage inventory returns sent to warehouses. It provides a clear overview of return statuses and key details, ensuring that inventory movements are tracked accurately from the store to the warehouse.

1.2 Step-by-Step Flow

1. Access & Authentication: When you navigate to the page, the system verifies your credentials. If you are not logged in, you will be redirected to the login screen.
2. Initial Data Load: Once authenticated, the system automatically retrieves and displays the current list of stock returns, along with the available lists of stores and warehouses.
3. Filtering: You can narrow down the list of returns using several criteria:

* Reference Code: Search by a specific return ID.

* Warehouse/Store: Select specific locations to view relevant returns.

* Date Range: Use the "From" and "To" date pickers to view returns within a specific timeframe.

* Status: Filter by the current stage of the return (e.g., Draft, Confirmed, Sent, Approval, or Cancelled).

4. Validation: If you enter a "From Date" that is later than the "To Date," the system will display an alert to correct the range before searching.
5. Search Execution: Clicking the search button updates the table to show only the records matching your selected filters.
6. Navigation: You can switch between the "Warehouse" view (current page) and the "Franchisee" view, or click "New Stock Order" to start a new return process.

1.3 Key Concepts

- Reference Code: A unique, system-generated identifier for every stock return, used for easy tracking and auditing.
- Workflow State: The current stage of a return process. This helps users identify if a return is still being prepared (Draft), waiting for review (Approval), or completed (Sent/Confirmed).
- Date Range Validation: A safety feature that ensures search criteria are logical, preventing errors caused by selecting an end date that occurs before a start date.
- Inventory Tabs: A navigation tool that allows users to toggle between different types of return lists (Warehouse vs. Franchisee) without leaving the inventory module.

1.4 Business Value

This feature streamlines inventory management by providing a single source of truth for all stock returns. By offering robust filtering and clear status tracking, it reduces the time spent searching for specific records and helps staff quickly identify which returns require attention or approval. This visibility minimizes the risk of lost inventory and ensures that the return process remains organized and accountable.

2. Logic

2.1 Overview

The Stock Returns List Page provides a centralized view for tracking inventory items being returned from stores to warehouses. This feature allows users to view a comprehensive list of return records, filter them by specific criteria, and monitor their progress through the approval workflow.

2.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the page, the system verifies their login status. If the user is not logged in, they are automatically redirected to the login screen.
2. Initial Data Load: Once authenticated, the system automatically retrieves and displays the full list of stock returns.
3. Filter Selection: Users can refine the list using various filters, including reference codes, specific stores, warehouses, date ranges, or current workflow statuses.
4. Validation: When applying a date range, the system ensures the "From Date" is not later than the "To Date." If the dates are invalid, an alert notifies the user to correct the selection.
5. Search Execution: Upon clicking the search button, the system fetches the filtered data and updates the table. If no records match the selected criteria, the table remains empty while keeping the headers visible.
6. Data Display: The system maps the retrieved information into clear columns, including the return reference code, relevant dates (creation, sent, and approval), store and warehouse names, current status, and the user who created the record.

2.3 Key Concepts

- Stock Return: A unique record representing inventory being moved back from a store to a warehouse.
- Workflow State: The current stage of a return (e.g., draft, sent, or approved), which helps users track the progress of the return process.
- Reference Code: A unique identifier assigned to each stock return for easy tracking and lookup.
-

Filter Criteria: Tools provided to narrow down the list, such as date ranges and location selectors, to help users find specific records quickly.

2.4 Business Value

- Operational Efficiency: By providing a searchable, filtered list, staff can quickly locate specific return records without manually scanning through all inventory data.
- Improved Accountability: The inclusion of "Created By" and specific timestamp fields (Sent/Approved) ensures full visibility into who initiated a return and when it reached its final status.
- Error Reduction: Built-in validation for date ranges prevents common user input errors, ensuring that search results are always accurate and relevant.
- Streamlined Workflow: Centralizing the status of returns allows managers to easily identify pending items that require approval, helping to keep inventory records up to date.

3. Data

3.1 Overview

The Stock Returns List page provides a centralized view for tracking inventory items being sent back from stores to a warehouse. This feature allows staff to monitor the lifecycle of a return, from its initial creation to its final approval, ensuring transparency and accountability throughout the return process.

3.2 Step-by-Step Flow

1. Requesting the List: The system retrieves a list of all stock returns, organized by the date they were created, with the most recent entries appearing at the top.
2. Filtering and Pagination: Users can narrow down the list using specific filters, and the system displays the results in manageable pages to ensure the interface remains fast and easy to navigate.
3. Data Consolidation: The system gathers information from multiple sources—including the store of origin, the destination warehouse, and the user who initiated the request—to provide a complete summary for each return.
4. Displaying Details: The final list presents the return reference code, key dates (creation, shipment, and approval), the involved locations, the current status of the return, and the name of the staff member who created it.

3.3 Key Concepts

- Stock Return: A formal record representing inventory being moved from a store back to a warehouse.
-

Workflow State: The current status of a return (e.g., pending, sent, or approved), which helps track where the item is in the process.

- Reference Code: A unique identifier assigned to each return, making it easy to search for or discuss specific transactions.
- Pagination: A method of breaking a large list of records into smaller, readable pages to improve system performance and user experience.

3.4 Business Value

This feature improves inventory accuracy by providing clear visibility into the movement of goods. By tracking exactly when a return was initiated, sent, and approved, management can identify bottlenecks in the supply chain, reduce the risk of lost inventory, and maintain a clear audit trail of who is responsible for each return transaction.

BUSINESS REQUIREMENTS DOCUMENT

Store Opname - List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Opname List page is a centralized dashboard within the Inventory module that allows users to view, search, and manage stock-taking records. It provides a clear overview of all stock-taking activities across different stores, enabling users to track the progress of inventory audits from initial draft to final completion.

1.2 Step-by-Step Flow

1. Initial Load: When the user navigates to the page, the system automatically fetches the most recent stock-taking records to display in the table.
2. Filtering: Users can narrow down the list by entering a specific document number, selecting a date range, choosing a specific store, or filtering by the current status (e.g., Draft, Completed, Approved, or Cancelled).
3. Search: After setting the desired filters, the user clicks the "Search" button to refresh the table with the relevant results.
4. Sorting: Users can click on column headers (such as Date, Store, or Status) to sort the list in ascending or descending order to better organize the data.
5. Navigation:

– Users can click on a specific Document Number to view the full details of that particular stock-taking record.

– Users can click the "New Stock Opname" button to be redirected to a page where they can create a new inventory audit.

6. Pagination: If there are many records, the system breaks them into pages. Users can navigate through these pages to view older or additional records without cluttering the screen.

1.3 Key Concepts

– Stock Opname: The formal process of counting and verifying physical inventory against system records.

– Workflow Status: The current stage of an inventory record, which helps track progress (e.g., a "Draft" is still in progress, while "Completed" or "Approved" indicates the audit is finished).

– Filter Controls: Tools that allow users to isolate specific data based on criteria like time, location, or status.

– Pagination: A navigation feature that splits large lists into smaller, manageable pages to improve performance and readability.

– Sorting: The ability to reorder the list by clicking column headers, making it easier to find the most recent or relevant entries.

1.4 Business Value

This feature improves inventory accuracy and operational transparency by providing a single source of truth for all stock-taking activities. By allowing staff to quickly filter and locate specific audit records, the system reduces the time spent on administrative tasks and helps managers monitor the status of inventory audits across multiple store locations in real-time.

2. Logic

2.1 Overview

The Stock Opname List page is a centralized dashboard within the Lumi ERP system designed to help users manage and track inventory stock-taking activities. This feature allows users to view, search, and filter a list of stock opname records, providing clear visibility into the status and history of inventory audits across different store locations.

2.2 Step-by-Step Flow

1. Initial Load: When the user navigates to the Stock Opname page, the system automatically triggers a request to fetch the latest inventory audit records.
2. Applying Filters: Users can narrow down the list by entering specific criteria, such as a reference number, a date range, a specific store location, or the current status of the audit (e.g., draft, approved, or completed).
3. Data Retrieval: Upon clicking the "Search" button, the system queries the database, joins the relevant store information, and retrieves the matching records.
4. Displaying Results: The system presents the data in a clear table format, showing key details like the document number, date, store name, current status, and the user who last updated the record.
5. Pagination: If there are many records, the system breaks them into pages. Users can navigate through these pages to view additional results without losing their current search filters.

2.3 Key Concepts

- Stock Opname: The formal process of counting and verifying physical inventory against system records.
- Reference Number: A unique identifier assigned to each stock-taking document for easy tracking and retrieval.
- Workflow State: The current stage of the audit process, which helps users identify if a record is still in progress (Draft) or finalized (Completed).
- Filtering: The ability to refine the list of records based on specific parameters, ensuring users only see the information relevant to their current task.
-

Pagination: A navigation method that displays a limited number of records per page to keep the interface clean and improve system performance.

2.4 Business Value

- Improved Operational Efficiency: By providing a searchable and filterable list, staff can quickly locate specific audit documents, saving time during busy inventory cycles.
- Enhanced Transparency: The inclusion of "Status" and "Updated By" fields ensures accountability and provides clear insight into the progress of inventory audits across the organization.
- Better Decision Making: With easy access to historical audit data and current statuses, managers can better monitor store performance and identify discrepancies in inventory management more effectively.

3. Data

3.1 Overview

The Stock Opname List page is a centralized dashboard within the Lumi ERP system designed to help warehouse managers track and manage inventory audit processes. This feature allows users to view all existing stock-taking records, search for specific audits by their reference number or current status, and see which warehouse each audit is associated with.

3.2 Step-by-Step Flow

1. Initiate Search: The user enters a search term (such as a reference number or a status like "Pending" or "Completed") into the search bar and clicks the Search button.
2. Filter and Retrieve: The system processes the request by scanning the inventory audit records to find matches based on the provided search term.
3. Data Consolidation: The system gathers the relevant audit details, including the specific warehouse name linked to each record.
4. Display Results: The system presents the filtered list to the user, sorted by the most recently created audits first, along with a total count of the records found.

3.3 Key Concepts

- Stock Opname: A formal inventory audit process used to verify that the physical stock in the warehouse matches the records in the system.
- Reference Number: A unique identifier assigned to each specific stock-taking session, making it easy to track and locate individual audit records.
-

Status: The current stage of an audit (e.g., scheduled, in-progress, or finalized), which helps users understand the progress of their inventory checks.

- Warehouse Context: The specific location or facility where the stock-taking activity is taking place, ensuring clarity when managing multiple storage sites.

3.4 Business Value

This feature improves operational efficiency by providing a clear, searchable overview of all inventory audit activities. By allowing users to quickly filter by status or reference number, warehouse managers can spend less time searching for information and more time addressing inventory discrepancies. Sorting by the most recent records ensures that the team is always focused on the most current and relevant audit tasks.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Returns - List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Returns list page provides a centralized dashboard for users to view, search, and manage all returns related to franchise purchases. This page acts as a hub where staff can monitor the status of returns, quickly locate specific documents, and initiate the creation of new return requests.

1.2 Step-by-Step Flow

1. Accessing the Page: Users navigate to the page via the Inventory menu.
2. Filtering Results: Users can narrow down the list of returns using search criteria such as the Return Number, Order Number, Store, Supplier, Warehouse, Status, or specific date ranges.
3. Applying Filters: After entering search criteria, the user clicks the "Search" button to refresh the list with relevant data.
4. Viewing Data: The system displays a table containing key details for each return, including dates, associated stores/suppliers, and the current workflow status.
5. Navigating Details: Users can click on a specific "Return No" or "Order No" to jump directly to the detailed view of that specific document.
6. Pagination: If there are many returns, users can move through the list page-by-page using the pagination controls at the bottom.
7. Creating New Returns: Users can click the "New Franchise Purchase Return" button to open a menu of options for starting a new return process.

1.3 Key Concepts

- Workflow Status: A visual indicator (badge) that shows the current stage of a return (e.g., Draft, Sent, or Approved), helping users track progress at a glance.
- Pagination: A tool that breaks the list into smaller, manageable pages to ensure the system remains fast and easy to read.
- Source Order Reference: A link between the return and the original purchase order, allowing users to trace a return back to its origin.
- Filters: Search tools that allow users to isolate specific records based on business-relevant data like dates or locations.

1.4 Business Value

This feature streamlines inventory management by providing a single, organized view of all franchise returns. By enabling quick searching and direct navigation to order details, it reduces the time staff spend manually tracking down return documentation. The clear status tracking ensures that teams can easily identify which returns are pending action, improving overall operational efficiency and accountability in the supply chain.

2. Logic

2.1 Overview

The Franchise Purchase Returns list page provides a centralized view for users to browse, search, and manage returns made by franchises. This feature ensures that users can easily locate specific return records using filters and navigate through large volumes of data using pagination, all while maintaining secure access to the system.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies that the user is logged in. If the user is not authenticated, they are automatically redirected to the login page.
2. Data Retrieval: Once authenticated, the system collects the current search filters (such as reference codes or status) and the requested page number. It then requests the relevant list of purchase returns from the database.
3. Data Formatting: The system receives the raw return data and translates it into a user-friendly table format.
4. Display: The formatted information—including return numbers, dates, store locations, and current status—is displayed in the table for the user to review.
5. Interaction: If the user updates a filter or clicks to a different page, the system repeats the data retrieval and formatting steps to refresh the table with the new results.

2.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can view sensitive inventory return data.
- Filters: Search tools that allow users to narrow down the list by specific criteria, such as a return reference code or the current workflow status.
- Pagination: A navigation feature that breaks the list into smaller, manageable pages to improve performance and readability.
- Workflow State: The current status of a return (e.g., pending, approved, or sent), which helps users track the progress of each transaction.

2.4 Business Value

This feature improves operational efficiency by allowing staff to quickly audit and manage franchise returns. By providing a searchable, paginated list, users can spend less time hunting for specific records and more time processing inventory adjustments. The inclusion of clear status tracking and user attribution ensures accountability and transparency across the franchise supply chain.

3. Data

3.1 Overview

The Franchise Purchase Returns list page provides a centralized dashboard for your team to view and manage all items returned by franchises. This feature allows users to quickly locate specific returns, monitor their progress through the approval workflow, and see key details such as which store initiated the return, the associated supplier, and the current status of the request.

3.2 Step-by-Step Flow

1. Access the List: When you open the Franchise Purchase Returns page, the system automatically displays a list of all returns, sorted by the most recently created items first.
2. Apply Filters: You can narrow down the list by entering a specific return reference code, selecting a particular workflow status (e.g., pending or approved), or choosing a specific date range.
3. System Processing: The system processes your filters and retrieves the relevant records from the database.
4. Pagination: To keep the page easy to navigate, the system displays the results in manageable chunks, allowing you to browse through large volumes of data without performance issues.
5. View Details: The final list presents clear, readable information for each return, including the Return and Order numbers, dates of creation and approval, the store and supplier involved, and the current user responsible for the record.

3.3 Key Concepts

- Workflow State: The current stage of the return process, indicating whether a return is in progress, awaiting approval, or finalized.
- Reference Code: A unique identifier assigned to each return, used to easily track and cross-reference specific transactions.
- Pagination: A method of breaking down a long list of records into smaller, separate pages to ensure the screen remains organized and fast to load.
- Filtering: The ability to narrow down the displayed list based on specific criteria, such as dates or status, to find exactly what you need.

3.4 Business Value

This feature improves operational efficiency by providing a clear, searchable overview of all franchise returns. By enabling staff to quickly filter and locate specific return records, the system reduces the time spent on administrative tasks and helps ensure that returns are processed and approved in a timely manner. This transparency helps maintain accurate inventory records and strengthens the relationship between the franchise stores and the central warehouse.

BUSINESS REQUIREMENTS DOCUMENT

Store - Report Discrepancy Stocks List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Store - Report Discrepancy Stocks" page provides a centralized dashboard for inventory managers to view, search, and manage stock discrepancies. This feature allows users to filter through existing discrepancy reports using specific criteria—such as product details, document references, or status—and perform follow-up actions like editing reports or providing feedback directly from the list.

1.2 Step-by-Step Flow

1. Access the Page: Navigate to the "Inventory" section of the main menu and select the "Store" tab to view the discrepancy list.
2. Apply Filters: Use the filter bar to narrow down results by entering a Product SKU, Product Name, or Document Reference Code, or by selecting a date range, specific entity, or report status.
3. Execute Search: Click the "Search" button to retrieve the relevant records. The system will only process the filters that have been filled out.
4. Review Data: The table will update to display the filtered list, showing key details such as the date, entity, product information, quantity, and current status.
5. Manage Records:

* Click "Show" on any row to view the full details of a specific discrepancy.

* Use the "Action" dropdown menu to either "Edit" an existing report or "Add Feedback" to a record.

6. Additional Actions: Use the dedicated buttons to create a "New Report" or "Download" the current list for external reporting.

1.3 Key Concepts

- Discrepancy Stock: A record indicating a mismatch between recorded inventory levels and actual physical stock.
- Filter Bar: A set of search fields that allows users to isolate specific records without needing to browse the entire database.
- Document Reference Code: A unique identifier assigned to a specific discrepancy report for easy tracking and auditing.
- Entity: The specific store or warehouse location associated with the stock discrepancy.
- Status: The current lifecycle stage of a discrepancy report (e.g., pending, under review, or resolved).

1.4 Business Value

This feature streamlines inventory management by providing a clear, searchable view of stock issues. By enabling users to quickly filter for specific discrepancies and take immediate action—such as adding feedback or editing reports—the system reduces the time spent on manual reconciliation and improves the accuracy of inventory records. This ensures that store managers can resolve stock imbalances faster, ultimately leading to better inventory control and operational efficiency.

2. Logic

2.1 Overview

The "Report Discrepancy Stocks" page is a centralized dashboard within the Lumi ERP system that allows users to view and manage inventory discrepancies. This feature provides a clear, searchable list of stock issues, enabling staff to track, review, and respond to discrepancies efficiently.

2.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the page, the system automatically verifies their session. If the user is not logged in, they are redirected to the login screen.
2. Initial Data Load: Once authenticated, the system automatically fetches the first 20 discrepancy records to display in the table.
3. Filtering: Users can refine the list by applying filters such as Product SKU, Product Name, or Status. When the "Search" button is clicked, the system updates the table to show only the records that match the selected criteria.
4. Data Presentation: The system maps raw system data into a user-friendly table format, displaying key details like the date, product information, quantity, and current status.
5. Actionable Items: Each row in the table includes specific controls (such as "Show" and "Respond") that allow users to take immediate action on a specific discrepancy.

2.3 Key Concepts

- Discrepancy Stock: An inventory record indicating a mismatch between expected and actual stock levels.
- Filtering: The ability to narrow down the list of records based on specific criteria (e.g., searching by a specific product name or SKU) to find relevant information quickly.
- Pagination: A method of displaying data in smaller, manageable chunks (e.g., 20 records at a time) to ensure the page remains fast and easy to navigate.
- Status: The current state of a discrepancy (e.g., pending, under review, or resolved), which determines what actions are available to the user.

2.4 Business Value

This feature streamlines inventory management by providing a single source of truth for stock discrepancies. By allowing users to quickly search and filter through issues, the system reduces the time spent investigating stock errors. Furthermore, by providing direct "Respond" actions within the list, the feature ensures that discrepancies are addressed promptly, helping to maintain accurate inventory records and operational accountability.

3. Data

3.1 Overview

The "Report Discrepancy Stocks" feature provides a centralized view for store managers and staff to monitor inventory inconsistencies. It allows users to browse a list of products where the recorded stock levels do not match the actual physical count. This page ensures that inventory errors are visible, searchable, and manageable, helping the team maintain accurate stock records.

3.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies the user's identity. If the session is invalid, the user is redirected to the login screen.
2. Data Retrieval: Once authenticated, the system automatically fetches the list of reported stock discrepancies.
3. Filtering and Pagination: The system displays the data in manageable chunks (defaulting to 20 items at a time). Users can apply filters, such as the current status of the discrepancy, to narrow down the list.
4. Information Display: The system retrieves and displays key details for each entry, including the product name, its unique identification code (SKU), the expected versus actual quantity, the reason for the discrepancy, and the current status of the report.
5. Result Presentation: The final list is presented to the user, including a total count of records to help with navigation.

3.3 Key Concepts

- Discrepancy Stock: An inventory record where the physical count in the store differs from the quantity recorded in the system.
- SKU (Stock Keeping Unit): A unique code used to identify and track specific products within the inventory.
- Pagination: A method of breaking a large list of data into smaller, easier-to-read pages to improve performance and usability.
- Status: The current state of a discrepancy report (e.g., pending review, resolved, or under investigation).

3.4 Business Value

This feature is essential for maintaining inventory integrity. By providing a clear, searchable list of discrepancies, it enables store staff to:

* Identify Shrinkage: Quickly spot patterns of missing or excess stock.

* Improve Accuracy: Facilitate faster reconciliation of inventory records.

* Enhance Accountability: Track the status of reported issues from discovery to resolution, ensuring that no inventory error is overlooked.

BUSINESS REQUIREMENTS DOCUMENT

Store - Stock Transfer List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Transfer List page is a centralized dashboard within the Inventory module that allows users to view, search, and manage all stock movement records. It provides a clear overview of transfers between locations, enabling users to quickly find specific transactions and navigate to detailed information for further action.

1.2 Step-by-Step Flow

1. Initial Load: When the user navigates to the page, the system automatically fetches and displays the most recent stock transfers.
2. Filtering: Users can narrow down the list by entering specific criteria (such as reference codes or date ranges) or selecting options from dropdown menus (such as status, transfer type, or specific locations).
3. Search: After setting filters, the user clicks the Search button to refresh the table. This updates the list to show only matching records and resets the view to the first page of results.
4. Sorting: Users can click on any column header (e.g., Date, Status, or Reference Code) to sort the list. Clicking once sorts the data in ascending order; clicking again reverses it to descending order.
5. Navigation: Users can click on any row in the table to open the specific details page for that transfer.
6. Pagination: If there are many records, the system breaks them into pages. Users can move between these pages using the pagination controls at the bottom of the table without losing their current filter settings.
7. Create New: A dedicated button is available to quickly navigate the user to the "New Stock Transfer" page to initiate a new transaction.

1.3 Key Concepts

- Stock Transfer: A record representing the movement of inventory items from one location to another.
- Filter Bar: A set of search and selection tools that allows users to isolate specific transfers based on criteria like date, status, or location.
- Pagination: A navigation feature that splits a large list of records into smaller, manageable pages to improve performance and readability.
- Status Badge: A visual indicator (color-coded) that shows the current state of a transfer (e.g., pending, completed, or in-transit).
- Sortable Columns: Table headers that allow users to organize data alphabetically or chronologically to find information faster.

1.4 Business Value

This feature streamlines inventory management by providing a "single source of truth" for all stock movements. By offering robust search and filtering capabilities, it reduces the time staff spend hunting for specific transfer records. The ability to easily sort and navigate through large volumes of data ensures that warehouse and store managers can maintain accurate inventory visibility and respond quickly to operational needs.

2. Logic

2.1 Overview

The Stock Transfer List page is a centralized dashboard within the Lumi ERP system that allows users to view, search, and navigate through all inventory stock transfers. The page ensures that only authorized users can access the data and provides a dynamic interface where users can filter transfers by location and browse through results using pagination.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies the user's identity. If the user is not logged in, they are automatically redirected to the Login page.
2. Load Filter Options: Once authenticated, the system retrieves a list of all available store locations to populate the "From" and "To" dropdown menus in the filter bar.
3. Fetch Data: The system requests the list of stock transfers based on the user's current search filters and page number.
4. Display Results: The retrieved data is processed and displayed in a table, showing key details such as reference codes, transfer types, dates, locations, status, and the user who initiated the transfer.
5. Interaction: If the user updates the search filters or changes the page, the system repeats steps 3 and 4 to refresh the table with the relevant information.

2.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can view sensitive inventory data.
- Filtering: The ability to narrow down the list of transfers by selecting specific "From" or "To" locations.
- Pagination: A navigation tool that breaks large lists of data into smaller, manageable pages, allowing users to move through results without overwhelming the screen.
- Workflow State: The current status of a transfer (e.g., pending, completed), which is visually highlighted to help users quickly identify the progress of each item.

2.4 Business Value

This feature provides inventory managers and staff with a clear, organized view of stock movement across the organization. By enabling quick searching and filtering, it reduces the time spent locating specific transfer records. Furthermore, the integration of pagination and status tracking ensures that the system remains performant and easy to navigate, even as the volume of stock transfers grows over time.

3. Data

3.1 Overview

The Stock Transfer List page provides a centralized view for users to browse and manage all inventory movements within the Lumi ERP system. This feature allows staff to quickly locate specific transfers, monitor their progress, and view key details such as origin, destination, and current status in a clear, organized table format.

3.2 Step-by-Step Flow

1. Requesting Data: When you open the page, the system automatically retrieves a list of stock transfers. You can use the search function to filter these results by reference code or specific locations.
2. Processing: The system gathers the relevant transfer records, including details about the locations involved and the user who created the request.
3. Displaying Results: The information is presented in a table. If no records match your search, the table will simply appear empty rather than showing an error.
4. Navigation: If there are many transfers, the system uses pagination to break the list into manageable pages, allowing you to move through the records easily.
5. Interaction: Each row in the table contains a hidden identifier that allows you to click on a specific transfer to open its full details for further action.

3.3 Key Concepts

- Reference Code: A unique identifier assigned to each stock transfer for easy tracking and searching.
- Workflow State: The current status of a transfer (e.g., pending, in transit, or completed), which is visually highlighted with a color-coded badge.
- Pagination: A navigation tool that splits large lists of data into smaller, readable pages to improve performance and usability.
- Denormalized Data: A method of combining related information (like location names and user names) into a single view so that the table displays human-readable text instead of complex internal codes.

3.4 Business Value

This feature improves inventory visibility and operational efficiency by providing a single source of truth for all stock movements. By enabling quick searching and clear status tracking, staff can reduce the time spent looking for information, minimize errors in stock handling, and maintain better control over inventory levels across different locations.

BUSINESS REQUIREMENTS DOCUMENT

Store - Stock Reservations

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Store Stock Reservations feature provides a centralized view for tracking inventory that has been set aside for specific purposes. This page allows users to monitor reserved stock across different store locations, filter by date ranges or specific products, and quickly navigate to related work orders or product details.

1.2 Step-by-Step Flow

1. Authentication: Upon opening the page, the system verifies your identity. If you are not logged in, you will be automatically redirected to the login screen.
2. Initialization: The system automatically loads the list of available stores to populate the filter dropdown and performs an initial search to display all current stock reservations without requiring manual input.
3. Filtering: You can narrow down the list of reservations using the filter bar, which includes:

* A date range (Start and End dates).

* Product identifiers (SKU or Name).

* A specific store location (required).

4. Search: After adjusting your filters, clicking the "Search" button updates the table instantly to show only the relevant records.
5. Navigation: You can click on specific items in the table to view more details:

* Clicking a Reference Code takes you directly to the associated work order.

* Clicking a Product SKU takes you to the product detail page.

1.3 Key Concepts

- Stock Reservation: Inventory that has been allocated or "held" for a specific work order or business requirement.
- Reference Code: A unique identifier linked to the source document (such as a work order) that triggered the stock reservation.
- SKU (Stock Keeping Unit): A unique code used to identify and track specific products in the inventory.
- Filter Parameters: The criteria (dates, product info, store) used to refine the list of reservations displayed in the table.

1.4 Business Value

This feature improves inventory accuracy and operational efficiency by providing clear visibility into reserved stock. By allowing staff to quickly filter and locate reservations, the system helps prevent stockouts and ensures that inventory is correctly allocated to the right work orders. The ability to jump directly from a reservation to a work order or product page streamlines the workflow for inventory managers and store staff, reducing the time spent searching for information.

2. Logic

2.1 Overview

The Stock Reservations feature provides a centralized view for tracking inventory that has been set aside. When a user navigates to the page, the system automatically verifies their identity and populates a list of current reservations. Users can refine this list using various filters, such as date ranges, specific products, or store locations, ensuring they can quickly find the information they need to manage stock effectively.

2.2 Step-by-Step Flow

1. Authentication: Upon opening the page, the system checks if the user is logged in. If the user is not authorized, they are automatically redirected to the login screen.
2. Initialization: Once authenticated, the system retrieves a list of available stores to populate the "Select Store" filter dropdown.
3. Automatic Data Load: The system immediately performs an initial search to display all current stock reservations without requiring the user to manually click a search button.
4. Filtering: When a user enters criteria (such as a date range, product name, or store), the system updates the view by sending these specific filters to the database and refreshing the table.
5. Data Display: The system maps the retrieved reservation details—including reservation dates, product information, quantities, and store names—into a clear, readable table format.

2.3 Key Concepts

- Stock Reservation: A record indicating that a specific quantity of a product has been set aside at a particular store location.
- Filter Criteria: Search parameters (like date, product SKU, or store) that allow users to narrow down the list of reservations.
- Authentication: A security check that ensures only logged-in users can access sensitive inventory data.
- Automatic Retrieval: A user-friendly design choice where the system fetches and displays data immediately upon page load, saving the user an extra click.

2.4 Business Value

This feature improves inventory accuracy and operational efficiency by providing real-time visibility into reserved stock. By automating the data retrieval process and offering intuitive filtering, staff can quickly identify which products are held for specific orders or purposes, reducing the risk of overselling and helping store managers make better-informed decisions about their available inventory.

3. Data

3.1 Overview

The Stock Reservations feature provides a centralized view for tracking items that have been set aside or reserved across different store locations. This tool allows staff to easily search, filter, and monitor reservation records, ensuring that inventory levels are accurately reflected and managed. By providing a clear overview of what is reserved, where it is held, and when it was requested, the system helps prevent overselling and improves stock accuracy.

3.2 Step-by-Step Flow

1. Initial Load: When the page opens, the system automatically retrieves the full list of current stock reservations and populates the "Select Store" dropdown menu with all available store locations.
2. Filtering: Users can narrow down the list of reservations by applying specific criteria, such as a date range, a specific product name or code (SKU), or by selecting a particular store.
3. Data Retrieval: Once filters are applied, the system sends these criteria to the database to fetch only the relevant records.
4. Display: The system presents the filtered results in a clear table format, showing key details like the reservation date, product information, quantity, and the associated store name.

3.3 Key Concepts

- Stock Reservation: A record indicating that a specific quantity of a product has been set aside at a particular store for a future purpose.
- Filter Criteria: The specific parameters (such as date, product name, or store) used to refine the list of reservations so users can find exactly what they need.
- Store Mapping: The process of linking a reservation record to a specific store location, ensuring that users can see exactly where the reserved inventory is physically held.
- SKU (Stock Keeping Unit): A unique identifier used to track a specific product within the inventory system.

3.4 Business Value

- Improved Inventory Accuracy: By tracking reservations in real-time, the business can avoid selling items that are already spoken for, reducing customer service issues.
- Operational Efficiency: Staff can quickly locate reservation details without manually searching through paper records or disparate systems, saving time during daily operations.
- Better Decision Making: With the ability to filter by store and date, managers can gain insights into reservation trends, helping them better allocate stock across different locations.

BUSINESS REQUIREMENTS DOCUMENT

Store - Stock Order List Page

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Store Stock Order List page provides a centralized view for users to manage and track inventory stock orders. This page allows users to browse all existing stock orders, apply specific filters to narrow down results, and navigate to detailed views for individual orders. It is designed to ensure that only authorized users can access the inventory data.

1.2 Step-by-Step Flow

1. Authentication Check: Upon loading the page, the system verifies the user's session. If the user is not logged in, they are automatically redirected to the login page.
2. Initial Data Load: Once authenticated, the page automatically fetches and displays a list of all stock orders.
3. Applying Filters: Users can refine the list using several criteria, including the Stock Order reference code, date ranges (From/To), specific stores, warehouses, or order statuses.
4. Executing Search: After setting the desired filters, the user clicks the "Search" button. The system then retrieves only the records that match the selected criteria.
5. Viewing Results: The results are displayed in a table format, showing key details such as the order date, status, store, warehouse, and financial amounts.
6. Navigation: Users can click on any row in the table to view the full details of a specific stock order, or click the "New Stock Order" button to begin creating a new request.

1.3 Key Concepts

- Filter-to-API Mapping: The system translates user-friendly filter selections (like "Store" or "Status") into specific data parameters that the database understands to fetch the correct records.
- Starts-with Matching: When searching by the Stock Order reference code, the system looks for matches that begin with the entered text, rather than searching for the text anywhere within the code.
- Status Badges: Visual indicators used in the table to quickly communicate the current state of an order (e.g., Draft, Confirmed, Received, or Cancelled).
- Sortable Columns: Users can click on table headers (such as Date or Status) to organize the list in ascending or descending order, making it easier to find specific information.
- Session Security: A mandatory background check that ensures only authenticated users can view or interact with sensitive inventory data.

1.4 Business Value

This feature streamlines inventory management by providing a high-visibility dashboard for tracking stock movement between warehouses and stores. By offering robust filtering and sorting capabilities, it reduces the time staff spend searching for specific orders, improves accuracy in monitoring order statuses, and ensures that inventory workflows remain organized and transparent.

2. Logic

2.1 Overview

The Stock Order List page provides a centralized view for users to browse, search, and manage warehouse stock orders. This feature ensures that only authorized users can access the list and provides a structured table to track order details, statuses, and financial information.

2.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the page, the system verifies their identity. If the user is not logged in, they are automatically redirected to the login screen.
2. Initial Data Load: Once authenticated, the system automatically fetches the first 20 stock orders to display in the table.
3. Applying Filters: Users can refine the list by entering specific criteria, such as order reference codes, date ranges, store or warehouse locations, and workflow statuses.
4. Search Execution: When the user clicks the "Search" button, the system sends a request to the server using only the active filters provided.
5. Table Update: The system receives the filtered results and updates the table, replacing the previous list with the new data.
6. Data Formatting: Each order is processed to ensure dates are readable, monetary values are formatted correctly, and status updates (such as "received" or "partially received") are clearly displayed as visual badges.

2.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can view sensitive inventory data.
- Filtering: The ability to narrow down a large list of orders based on specific attributes like date, location, or current status.
- Pagination: A method of displaying data in smaller, manageable chunks (e.g., 20 items at a time) to improve page performance.
-

Workflow State: The current progress of an order (e.g., pending, received, or partially received), which helps users track the lifecycle of their stock.

- Mapping: The process of taking raw system data and translating it into a user-friendly table format with clear labels and formatted values.

2.4 Business Value

This feature streamlines inventory management by providing a clear, searchable interface for tracking stock movement between warehouses and stores. By allowing users to quickly filter by status or date, the system reduces the time spent searching for specific orders, improves accuracy in monitoring order fulfillment, and ensures that financial data (such as order and receive amounts) is consistently visible and easy to interpret.

3. Data

3.1 Overview

The Stock Order List page provides a centralized view for users to browse, search, and manage stock orders within the Lumi ERP system. This feature allows users to quickly locate specific orders by applying various filters—such as order reference codes, date ranges, store or warehouse locations, and current workflow status—ensuring that inventory management remains organized and efficient.

3.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically verifies the user's session. If authorized, it fetches the initial list of stock orders.
2. Data Retrieval: The system requests data from the server, specifically filtering for "stock orders" to ensure only relevant records are retrieved.
3. Applying Filters: Users can refine the list by entering search criteria (like a reference code or date range) and clicking the "Search" button. The system sends these specific criteria to the server to narrow down the results.
4. Data Processing: Once the server returns the raw data, the system filters out any records that do not match the required "stock order" type and formats the information into a clean, readable layout.
5. Display: The processed data is populated into the Stock Order Table, allowing the user to view the relevant order details.
6. Updates: Any subsequent actions—such as changing filters, navigating through pages, or refreshing the view—trigger a new request to the server to update the table with the most current information.

3.3 Key Concepts

-

Stock Order: A specific type of inventory record that tracks the movement of goods between warehouses and stores.

- Filtering: The ability to narrow down a large list of orders based on specific criteria, such as date, location, or current status.
- Pagination: A method of breaking down a large list of records into smaller, manageable pages to improve performance and readability.
- Workflow State: The current stage of an order in its lifecycle (e.g., pending, in-transit, or received).
- Reference Code: A unique identifier used to track and locate a specific stock order document.

3.4 Business Value

This feature streamlines inventory operations by providing a high-performance, searchable interface for stock management. By allowing users to filter and paginate through large volumes of data, the system reduces the time spent searching for specific orders, minimizes manual errors, and provides real-time visibility into the status of stock movements across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Return

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Purchase Return feature provides a centralized dashboard for managing inventory returns and claims sent to suppliers. This screen allows users to view a list of all standard purchase returns, filter them by specific criteria (such as status, date range, or supplier), and navigate to detailed records for further action.

1.2 Step-by-Step Flow

1. Authentication Check: Upon loading the page, the system verifies the user's login status. If not logged in, the user is redirected to the login page.
2. Initial Data Load: Once authenticated, the system automatically retrieves and displays all standard purchase returns.
3. Filtering: Users can narrow down the list using various criteria, including document number, return type (Return or Claim), date ranges, warehouse, supplier, and workflow status (e.g., Draft, Approved).
4. Applying Search: After setting the desired filters, the user clicks the search button to refresh the list with the relevant records.
5. Sorting: Users can click any column header to sort the data in ascending or descending order.
6. Navigation: Users can click on a specific Document Number to view the full details of that individual return.
7. Pagination: The system displays records in groups of 20, allowing users to navigate through multiple pages of results.

1.3 Key Concepts

- Return vs. Claim: Two distinct categories for inventory adjustments; "Returns" typically involve sending physical goods back, while "Claims" may relate to discrepancies or quality issues.
- Workflow State: The current lifecycle stage of a return, which tracks progress from an initial "Draft" through to "Sent," "Approved," or "Cancelled."
- Filter Bar: A set of controls that allows users to isolate specific records without needing to search through the entire database manually.
- Document Number: A unique, system-generated identifier for every return, used as the primary reference for tracking and auditing.

1.4 Business Value

This feature streamlines the inventory management process by providing clear visibility into the status of all outgoing returns. By enabling quick filtering and sorting, staff can efficiently track the progress of claims and

returns, ensure that supplier interactions are documented, and maintain accurate inventory records. This reduces manual administrative effort and helps prevent errors in the return-to-supplier workflow.

2. Logic

2.1 Overview

The Purchase Return feature provides a centralized view for managing inventory returns to suppliers. It allows users to view, search, and filter purchase return records within the Lumi ERP system. The system ensures that only authorized users can access this information and provides a clean, organized table to track the lifecycle of each return—from creation to final approval.

2.2 Step-by-Step Flow

1. Authentication Check: When you navigate to the page, the system automatically verifies your login status. If you are not logged in, you will be redirected to the login screen.
2. Initial Data Load: Once authenticated, the system automatically loads a list of standard purchase returns (excluding fixed assets) to display in the table.
3. Search and Filter: You can use the search controls to narrow down the list. You may filter by document number, return type, warehouse, supplier, or current status.
4. Apply Filters: When you click the search button, the system collects your criteria, ignores any empty fields, and refreshes the table to show only the records that match your specific request.
5. Data Display: The system maps the retrieved information into the table, showing key details such as the document number, dates (created, sent, and approved), warehouse and supplier names, and the current workflow status.

2.3 Key Concepts

- Purchase Return: A record representing inventory being sent back to a supplier.
- Workflow State: The current stage of the return process (e.g., pending, sent, or approved), helping you track progress.
- Filter Criteria: Specific fields used to refine the list of returns, ensuring you only see the data relevant to your current task.
- Fixed Asset: A specific category of inventory that is excluded from the default view to keep the list focused on standard operational returns.

2.4 Business Value

This feature streamlines inventory management by providing a clear, searchable overview of all supplier returns. By automating the data retrieval and filtering process, it reduces manual effort, minimizes errors in tracking return statuses, and ensures that warehouse and procurement teams have real-time visibility into the movement of goods back to suppliers.

3. Data

3.1 Overview

The Purchase Return feature provides a centralized view of all items being returned to suppliers. This functionality allows your team to track the lifecycle of a return—from the initial creation of the request to its final approval—ensuring that inventory adjustments and supplier communications are transparent and well-documented.

3.2 Step-by-Step Flow

1. The system retrieves all purchase return records from the database, automatically sorting them by the most recently created entries first.
2. The system maps the internal database information into a clear, readable format for the user.
3. This information is then presented to the user, including key details such as the document reference number, the type of return, the warehouse involved, the supplier, and the current status of the request.
4. If the system successfully retrieves this data, it is displayed in the interface; if an error occurs, the system provides a notification that the list could not be loaded.

3.3 Key Concepts

- Purchase Return: A formal record documenting items sent back to a supplier, typically due to defects, overstock, or incorrect shipments.
- Workflow State: The current stage of the return process, indicating whether the request is pending, sent, or fully approved.
- Reference Code: A unique identifier assigned to each return document to make searching and auditing easier.
- Warehouse Name: The specific storage location from which the returned goods are being dispatched.

3.4 Business Value

This feature improves inventory accuracy and supplier accountability. By providing a clear, real-time overview of all returns, your team can quickly identify bottlenecks in the approval process, ensure that returned stock is properly accounted for, and maintain a reliable audit trail for all interactions with suppliers.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Orders (Standard)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Standard Purchase Order list feature provides a centralized dashboard for viewing and managing all standard asset purchase orders within the Lumi ERP system. This interface allows users to quickly locate specific orders using various search criteria and provides a high-level summary of order details, including their current status and progress regarding deliveries, invoices, and returns.

1.2 Step-by-Step Flow

1. Automatic Loading: When you first open the page, the system automatically retrieves and displays all standard purchase orders.
2. Applying Filters: You can narrow down the list by entering specific criteria, such as the internal reference code, supplier-provided reference number, date ranges, specific suppliers, receiving warehouses, or the current workflow status (e.g., Draft, Sent, or Received).
3. Executing Search: Once your filters are set, clicking the "Search" button triggers the system to refresh the list and display only the orders that match your criteria.
4. Reviewing Data: The results are presented in a table format, showing key information like dates, amounts, and the current status of each order.
5. Monitoring Progress: The table includes summary columns that indicate if an order is closed and provide quick counts for related activities like deliveries, invoices, and returns.

1.3 Key Concepts

- Reference Code: The unique internal identifier generated by the system for each purchase order.
- Supplier Reference Number: The external tracking number provided by the supplier, used for matching the order against their documentation.
- Workflow Status: The current stage of the order in the procurement process, categorized as Draft, Sent, or Received.
- Derived Counts: Calculated totals displayed in the list that show how many invoices, deliveries, or returns are associated with a specific order, helping you track fulfillment progress at a glance.
- Filter Bar: A set of input fields and dropdowns that allow you to refine the list of orders based on your specific reporting or operational needs.

1.4 Business Value

This feature improves operational efficiency by providing a "single source of truth" for all standard purchase orders. By enabling quick searching and filtering, procurement teams can spend less time hunting for documents and more time managing supplier relationships. Additionally, the inclusion of status badges and activity counts (invoices, deliveries, returns) allows users to proactively identify bottlenecks or incomplete orders, ensuring better control over the inventory procurement lifecycle.

2. Logic

2.1 Overview

The Purchase Order browsing feature provides a centralized view for managing standard asset procurement. It allows users to view a comprehensive list of all purchase orders, with the ability to filter results by specific suppliers or warehouses. The system automatically pulls in relevant details and provides a quick summary of related activities—such as returns, invoices, and deliveries—directly within the list view.

2.2 Step-by-Step Flow

1. Data Retrieval: When the page loads, the system fetches all standard purchase orders. If you have selected a specific supplier or warehouse filter, the system narrows the results to match those criteria.
2. Information Enrichment: For every order found, the system automatically looks up the human-readable names for the associated warehouse and supplier, replacing internal ID codes with names that are easy to identify.
3. Activity Calculation: The system scans related records to count how many returns, invoices, and deliveries are linked to each specific purchase order.
4. Display: All this information is organized into a clear table, showing key dates, status, financial totals, and the activity counts, allowing you to see the progress of each order at a glance.

2.3 Key Concepts

- Filtering: The ability to narrow down the list of orders by choosing a specific supplier or warehouse to focus on relevant data.
- Enrichment: The process of automatically pulling in descriptive names (like "Warehouse A" or "Supplier B") so you don't have to look up what a numerical ID represents.
- Derived Counts: A summary feature that calculates the number of related documents (returns, invoices, and deliveries) for each order, providing immediate visibility into the order's lifecycle.
- Workflow State: The current status of the purchase order, helping you track where it sits in the procurement process.

2.4 Business Value

- Improved Efficiency: By displaying counts for returns, invoices, and deliveries directly in the list, users can identify the status of an order without needing to open each individual record.
- Better Decision Making: The ability to filter by warehouse or supplier allows procurement teams to quickly assess supply chain performance and inventory distribution.
- Enhanced Clarity: Replacing technical identifiers with clear names and organized columns ensures that the information is accessible and easy to interpret for all team members.

3. Data

3.1 Overview

The Purchase Order browsing feature provides a centralized dashboard for managing "Standard Asset" purchase orders within the Lumi ERP system. This tool allows users to efficiently search, filter, and view the status of all standard procurement activities. Beyond basic order details, the system automatically calculates and displays the volume of related activity—such as deliveries, invoices, and returns—giving users an immediate snapshot of an order's progress without needing to open individual records.

3.2 Step-by-Step Flow

1. Request: The user initiates a search or navigates to the Purchase Order list.
2. Filtering: The system applies any user-defined criteria, such as specific reference codes, supplier names, order status, or date ranges.
3. Data Retrieval: The system fetches the relevant purchase orders, specifically filtering for "Standard" asset types.
4. Activity Calculation: For every order retrieved, the system automatically counts the number of associated deliveries, invoices, and returns linked to that specific order.
5. Formatting: The raw data is organized into a user-friendly format, mapping internal system codes to clear, readable columns (e.g., Status, Amount, and activity counts).
6. Display: The final list is presented to the user, sorted by the most recently created orders first.

3.3 Key Concepts

- Standard Asset: A specific category of purchase order used for routine procurement, distinct from other specialized order types.
- Workflow State: The current stage of the purchase order in its lifecycle (e.g., pending, approved, or completed).
-

Derived Counts: Automatically generated totals that show how many invoices, deliveries, or returns are tied to a single purchase order, providing instant visibility into the order's fulfillment status.

- Pagination: A method of displaying large amounts of data in smaller, manageable chunks to ensure the system remains fast and easy to navigate.

3.4 Business Value

- Improved Visibility: By displaying counts for invoices, deliveries, and returns directly in the list view, staff can instantly identify which orders are fully processed and which require attention.
- Operational Efficiency: Users can quickly locate specific orders using flexible search and filter options, reducing the time spent manually tracking procurement documents.
- Better Decision Making: Having a clear, real-time overview of order statuses and associated documentation helps teams manage supplier relationships and inventory replenishment more effectively.

BUSINESS REQUIREMENTS DOCUMENT

Company - Stock Outgoings List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Stock Outgoings List" page provides a centralized dashboard for managing inventory departures. It allows users to view, search, and filter all outgoing stock records within the company. This page is designed to help inventory managers quickly locate specific outgoing shipments, track their status, and navigate to detailed records for further action.

1.2 Step-by-Step Flow

1. Initial Load: When you first open the page, the system automatically displays a list of all stock outgoings, sorted by the most recently created items first.
2. Filtering: You can narrow down the list using the filter bar. You may search by reference code, specify a date range, or select specific entities, sources (stores/warehouses), or document statuses.
3. Applying Filters: Once you have entered your criteria, click the "Search" button to refresh the list. The system will only show records that match your selections.
4. Sorting: You can click on any column header (such as Date, Status, or Entity) to re-sort the list. Clicking once sorts the list in ascending order; clicking again reverses it to descending order.
5. Pagination: The list displays 20 records at a time. You can use the pagination controls at the bottom of the page to move between pages or jump to specific sections of the list.
6. Viewing Details: If you need to see more information about a specific shipment, simply click on any row in the table to be taken directly to that document's details page.
7. Creating New Records: If you need to initiate a new outgoing shipment, click the "New Stock Outgoing" button to be redirected to the creation form.

1.3 Key Concepts

- Reference Code: A unique identifier generated by the system for every outgoing stock document, used to track and locate specific shipments.
- Source: The specific location (either a store or a warehouse) from which the stock is being removed.
- Status: The current stage of the outgoing document, which can be Draft, Confirmed, Approved, or Cancelled.
- Entity: The legal business unit or company associated with the stock movement.
- Empty State: A helpful message displayed if your search filters return no results, providing an easy way to clear your filters and reset the view.

1.4 Business Value

This feature streamlines inventory management by providing a high-level overview of all stock departures. By offering robust search and filtering capabilities, it reduces the time spent manually hunting for records. The ability to quickly sort and paginate through large volumes of data ensures that inventory teams can maintain accurate records and respond to operational needs with greater speed and efficiency.

2. Logic

2.1 Overview

The Stock Outgoings List Page provides a centralized view for tracking all inventory items leaving your facility. This feature allows warehouse staff and managers to easily browse, search, and filter outgoing stock records, ensuring better visibility into the movement of goods.

2.2 Step-by-Step Flow

1. Requesting Data: When you open the Stock Outgoings page, the system automatically requests a list of outgoing records.
2. Applying Filters: You can narrow down the list by entering a specific reference number in the search bar or by selecting a particular status (e.g., pending, completed) to view only relevant items.
3. Pagination: To keep the page performance fast and easy to read, the system displays the records in manageable chunks (pages). You can navigate through these pages to view older or newer entries.
4. Data Display: The system retrieves the relevant records and organizes them into a clear table format, showing key details such as the reference code, the date the outgoing was created, and its current status.

2.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, numbered pages so you don't have to scroll through an endless list.
- Filtering: The ability to refine the list of results based on specific criteria, such as status or reference numbers, to find exactly what you need quickly.
- Reference Number: A unique identifier assigned to each outgoing stock movement, used to track and verify specific shipments.
- Status: The current stage of an outgoing shipment in the workflow, helping you identify which items are still in progress and which have been finalized.

2.4 Business Value

- Improved Efficiency: By providing search and filter capabilities, staff can locate specific outgoing shipments in seconds rather than manually scanning through logs.

- Better Inventory Oversight: Real-time visibility into outgoing stock helps management monitor warehouse activity and identify potential bottlenecks in the shipping process.
- Scalability: The use of pagination ensures that the system remains fast and responsive, even as your company's volume of outgoing stock grows over time.

3. Data

3.1 Overview

The Stock Outgoings List page provides a centralized view for tracking all inventory leaving your facilities. This feature allows warehouse managers and staff to easily browse, search, and organize outgoing stock records. By providing robust filtering and pagination, the system ensures that users can quickly locate specific shipments or monitor recent activity without being overwhelmed by large volumes of data.

3.2 Step-by-Step Flow

1. Initial Load: When you open the page, the system automatically retrieves the most recent outgoing stock records, sorted by date (newest first).
2. Search and Filter: You can narrow down the list by entering a specific reference number, selecting a status, or defining a date range.
3. Data Retrieval: The system sends your criteria to the database to fetch the relevant records.
4. Display: The results are presented in a clear list, showing key details such as the reference number, current status, destination warehouse, date of creation, and the total number of items included in the shipment.
5. Navigation: If there are many records, you can use the pagination controls to move through the list page by page.

3.3 Key Concepts

- Stock Outgoing: A record representing inventory that has been dispatched or is scheduled to leave a warehouse.
- Reference Number: A unique identifier assigned to each outgoing shipment for easy tracking and cross-referencing.
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Filtering: The ability to refine the list of records based on specific criteria, such as date, status, or destination.
- Sorting: The ability to reorder the list based on specific columns, such as the date the record was created.

3.4

Business Value

This feature improves operational efficiency by providing real-time visibility into outgoing inventory. By enabling staff to quickly filter and find specific shipments, the system reduces the time spent on administrative tasks and helps prevent errors in tracking. Furthermore, the organized list view supports better decision-making by allowing managers to monitor warehouse throughput and verify the status of outgoing goods at a glance.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Standard List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Franchise Purchase Orders - Standard List Page" provides a centralized view for managing standard external purchase orders within the Lumi ERP system. This page allows users to browse, search, and filter purchase orders, providing clear visibility into order status, financial amounts, and key dates. It is designed to help inventory managers efficiently track the lifecycle of standard franchise orders from creation to receipt.

1.2 Step-by-Step Flow

1. Accessing the Page: Upon loading the page, the system automatically retrieves and displays the most recent standard purchase orders.
2. Filtering and Searching: Users can narrow down the list by entering a specific Document Number or by using various filters, such as date ranges, store, supplier, status, or source. Clicking the "Search" button updates the table to show only the matching records.
3. Browsing the List: The table displays key details for each order, including reference numbers, store and supplier names, order/receive amounts, and current workflow status.
4. Sorting: Users can click on column headers (such as Document Number, Created At, or Status) to sort the list in ascending or descending order to better organize their view.
5. Navigation: Users can move through the list using the pagination controls at the bottom of the page.
6. Viewing Details: Clicking on a specific Document Number link will take the user to a dedicated detail page for that specific purchase order.
7. Switching Views: Users can toggle between "Standard" and "Internal" purchase order lists using the navigation tabs at the top of the page.

1.3 Key Concepts

- Standard Purchase Order: An external order placed with a supplier, distinct from internal warehouse transfers.
- Filter Bar: A set of search and selection tools that allow users to find specific orders based on criteria like date, store, or supplier.
- Workflow Status: A visual indicator (badge) that shows the current stage of an order (e.g., "Ordered") and highlights if an order has been only partially received.
- Pagination: A navigation feature that breaks the list into manageable pages, ensuring the system remains fast and easy to read.
-

Sorting: The ability to reorder the list by clicking column headers, making it easier to find the oldest, newest, or most urgent orders.

1.4 Business Value

This feature streamlines inventory management by providing a single, organized source of truth for all standard franchise purchase orders. By enabling quick searching and filtering, it reduces the time staff spend looking for order information. Furthermore, the clear display of order amounts and status updates helps teams maintain better financial oversight and ensures that store supply needs are tracked accurately and transparently.

2. Logic

2.1 Overview

The Franchise Purchase Order Standard List Page provides a centralized view for users to browse and manage standard purchase orders. This feature allows users to efficiently locate specific orders using search and pagination tools, ensuring that all relevant information—such as order status, supplier details, and financial amounts—is clearly visible in a structured table format.

2.2 Step-by-Step Flow

1. Request Data: When you open the page or apply a search filter, the system requests a list of purchase orders specifically categorized as "standard" orders.
2. Pagination: The system retrieves the data in manageable chunks (pages) to ensure the list remains easy to navigate.
3. Data Processing: The system takes the raw order information and organizes it into a clean, readable table format.
4. Formatting: Dates are converted into a standard readable format, and financial figures are displayed as currency.
5. Status Mapping: Internal system status codes (like "placed") are translated into user-friendly labels (like "Ordered") to make the current state of an order immediately clear.
6. Display: The final table is rendered, showing key details such as the document number, supplier, store, and current order status.

2.3 Key Concepts

– Standard Purchase Orders: A specific category of orders (external standard) that this page is dedicated to tracking.

–

Document Number: A unique identifier for each order that acts as a clickable link, allowing you to navigate directly to the full details of that specific purchase order.

- Status Badge: A visual indicator that shows the current progress of an order (e.g., "Ordered"). If an order has been partially received, a distinct badge will highlight this status.
- Pagination: A navigation feature that breaks the list of orders into smaller pages, preventing the need to scroll through an excessively long list.
- Search: A tool that allows you to quickly filter the list to find specific orders by entering keywords.

2.4 Business Value

This feature streamlines inventory management by providing a dedicated, high-visibility workspace for standard franchise orders. By offering clear status tracking, easy searchability, and direct links to order details, it reduces the time spent searching for information and helps staff quickly identify which orders are pending, completed, or partially received. This improves operational efficiency and ensures better oversight of the procurement process.

3. Data

3.1 Overview

The Franchise Purchase Order List Page provides a centralized view for managing standard purchase orders within the Lumi ERP system. This feature allows users to browse, search, and filter through all standard franchise orders, ensuring that store managers and procurement teams have clear visibility into the status, financial details, and timelines of their orders.

3.2 Step-by-Step Flow

1. Data Retrieval: The system fetches the complete list of franchise purchase orders from the database.
2. Filtering: The system automatically filters the list to display only "Standard" purchase orders, ensuring the view remains focused on the relevant order type.
3. Data Mapping: Each order is processed to translate raw system data into a user-friendly format, including formatting dates, currency values, and status labels.
4. Display: The processed data is presented in a table format, where each row represents a single purchase order.
5. Interaction: Users can click on the Document Number to navigate to the specific details of any order, or use search and filter tools to narrow down the list as needed.

3.3 Key Concepts

-

Standard Purchase Order: A specific category of order used for external procurement, which is the primary focus of this list view.

- Status Badge: A visual indicator (such as "Ordered") that provides an immediate update on the current stage of the purchase order.
- Partial Receipt: A status indicator used when an order has been delivered in multiple shipments, helping users track incomplete deliveries.
- Currency Formatting: Financial figures (Order Amount and Receive Amount) are automatically formatted to ensure they are easy to read and compare.
- Document Number: A unique identifier for each order that serves as a direct link to the full order details.

3.4 Business Value

- Improved Efficiency: By providing a dedicated list page for standard orders, users can quickly locate specific documents without navigating through unrelated order types.
- Enhanced Visibility: Clear status badges and receipt tracking (including partial shipments) allow teams to proactively manage inventory and address potential supply delays.
- Data Accuracy: Automated formatting of currency and dates reduces manual interpretation errors, ensuring that financial reporting and order tracking remain consistent across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Stock Return (Warehouse)

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "New Stock Return (Warehouse)" feature provides a dedicated page within the Inventory module to manage the return of stock from a store back to a warehouse or internal supplier. This page allows users to document which items are being returned, the quantities involved, and the reasons for the return, ensuring that inventory records remain accurate throughout the process.

1.2 Step-by-Step Flow

1. Access the Module: Navigate to the Inventory module using the main navigation panel.
2. Enter Return Details: Fill out the warehouse form, which includes selecting the source store, the destination (internal supplier or warehouse), a reference code, and any relevant notes.
3. Add Products: Use the product table to list the items being returned. For each item, specify the product, the current store quantity, the quantity being returned, and the reason for the return.
4. Validate Quantities: Ensure that the return quantity for each item does not exceed the available store quantity.
5. Save or Cancel:

– Click Save to submit the return request. The system will record the data, set the status to "Draft," and redirect you to the confirmation page.
– Click Cancel to discard all changes and return to the main Stock Return list.

1.3 Key Concepts

– Workflow Status: A tracker that displays the current stage of the return (e.g., Draft, Confirmed, Sent, Approved), helping users monitor the progress of the request.
– Stock Return Form: The primary interface for capturing administrative details like the origin store, destination warehouse, and reference documentation.
– Product Table: A dynamic list where users can add multiple items to a single return request, including specific details for each product line.
– Validation: A built-in check that prevents users from returning more stock than is currently recorded as available in the store.

1.4 Business Value

This feature streamlines the inventory reconciliation process by providing a standardized way to move stock back into the supply chain. By digitizing these returns, the business gains better visibility into why stock is being returned, reduces manual data entry errors, and ensures that inventory levels are accurately updated across all locations.

2. Logic

2.1 Overview

The "New Stock Return (Warehouse)" feature allows warehouse staff to formally initiate a return of inventory. This process captures the details of the return, including where the items are coming from, where they are being sent, and the specific reasons for returning each product. When a user submits this form, the system creates a digital record of the return, initially setting it to a "draft" status to ensure accuracy before final processing.

2.2 Step-by-Step Flow

1. Data Entry: The user fills out the return form, providing details such as the source store, the destination supplier or warehouse, a reference code, and any relevant notes.
2. Item Specification: The user adds the specific products being returned, including the quantity currently in the store, the quantity being returned, and the reason for the return for each item.
3. Submission: Upon clicking the save button, the system collects all form data and sends it to the server.
4. Validation and Creation: The system validates the information and creates a new "Stock Return" record in the database, automatically assigning it a "draft" status.
5. Item Processing: The system links each individual product item to the main return record and saves them to the database.
6. Confirmation: Once all data is successfully saved, the system confirms the creation of the record, allowing the user to proceed to the next stage of the workflow.

2.3 Key Concepts

- Workflow State: A status indicator that tracks the progress of the return; all new returns start as a "draft" to allow for review.
- Reference Code: A unique identifier or document number used to track the return for auditing and organizational purposes.
- Internal Supplier/Warehouse: The designated destination for the returned stock, ensuring the inventory is routed to the correct location.
- Return Reason: A mandatory explanation for each item returned, which helps management analyze why stock is being moved back to the warehouse.

2.4 Business Value

This feature streamlines inventory management by providing a standardized, digital way to track stock movements. By requiring specific reasons for returns and maintaining a clear audit trail (via reference codes and workflow

states), the business can better identify trends in product returns, reduce manual data entry errors, and ensure that returned inventory is accurately accounted for as it moves back into the supply chain.

3. Data

3.1 Overview

The "New Stock Return (Warehouse)" feature allows staff to formally initiate the process of returning inventory from a retail store back to a central warehouse or internal supplier. This system ensures that all returned items are accurately tracked, documented, and linked to a specific reason for the return, providing clear visibility into inventory movement across the organization.

3.2 Step-by-Step Flow

1. Initiation: The user fills out the stock return form, providing details such as the source store, the destination warehouse or supplier, and any relevant reference codes or notes.
2. Item Selection: The user adds the specific products being returned, including the quantity being sent and the reason for each return (e.g., damaged, overstock, or expired).
3. Validation: The system checks that all mandatory information—such as the source store and the list of products—is present before proceeding.
4. Processing: Once submitted, the system creates a formal record of the return and logs each individual item associated with that return.
5. Confirmation: The system saves the transaction securely and provides a confirmation that the stock return has been successfully recorded.

3.3 Key Concepts

- Stock Return: A formal record documenting the movement of inventory from a store back to a warehouse or internal supplier.
- Line Items: The individual products included in a return, each tracked with its own quantity and specific reason for being returned.
- Workflow State: The current status of the return, which helps track the progress of the request from initiation to completion.
- Reference Code: A unique identifier or tracking number used to easily locate or cross-reference the return in the future.

3.4 Business Value

-

Inventory Accuracy: By requiring a structured return process, the business maintains a precise count of stock levels, preventing discrepancies between store and warehouse records.

- Accountability: Every return is linked to a specific reason and source, making it easier to identify trends, such as recurring product defects or overstock issues at specific locations.
- Operational Efficiency: Automating the documentation process reduces manual paperwork and ensures that warehouse teams receive clear, standardized information about incoming shipments.

BUSINESS REQUIREMENTS DOCUMENT

Store - New Stock Opname

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Stock Opname" feature allows staff to initiate a stock-taking process for a specific store. This page provides a structured way to record physical inventory counts, compare them against system records, and document any discrepancies. It is designed to help businesses maintain accurate inventory levels by identifying and adjusting for missing or excess stock.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves necessary setup information (such as available stores, product categories, and suppliers) to populate the form options.
2. Form Setup: The user selects the target store and sets the document date. The system defaults the status to "DRAFT" to indicate the process has begun but is not yet finalized.
3. Autofill Configuration: The user can define criteria to automatically pull a list of products into the form. This includes filtering by product type, brand, supplier, or recent movement history, and choosing whether to include items currently showing zero stock.
4. Manual Entry & Adjustment: The user adds products to the list, entering the "counted quantity" for each. The system ensures that each product is only listed once to prevent calculation errors.
5. Validation: Before saving, the system checks that all required fields are filled and that no negative numbers have been entered for counted quantities.
6. Submission: Once the user clicks "Save," the system processes the data and redirects the user to the main list of stock-taking documents.

1.3 Key Concepts

- Stock Opname: The formal process of counting physical inventory to verify that it matches the quantities recorded in the system.
- Draft Status: A temporary state for a document that is still being edited and has not yet been officially confirmed or approved.
- Autofill Criteria: A set of filters used to quickly generate a list of products for counting, saving the user from having to add every item manually.
- Variance: The difference between the physical quantity counted by the staff and the quantity currently recorded in the system.
- Duplicate Prevention: A built-in safety check that prevents the same product from being added to the same stock-taking document multiple times, ensuring data integrity.

1.4 Business Value

- Improved Inventory Accuracy: By formalizing the stock-taking process, businesses can identify and correct discrepancies between physical stock and system records.
- Operational Efficiency: The "Autofill" feature significantly reduces the time required to prepare a stock-taking list by automatically pulling relevant products based on specific business rules.
- Error Reduction: Automated validation—such as preventing negative counts and duplicate product entries—ensures that the data submitted is clean and reliable for financial reporting.
- Better Decision Making: Accurate stock data allows management to make informed decisions regarding purchasing, restocking, and identifying potential inventory loss or theft.

2. Logic

2.1 Overview

The "New Stock Opname" feature allows staff to perform a physical inventory count at a specific store. This process ensures that the actual stock levels on the shelf match the records in the system. The feature includes an "autofill" capability to help users quickly pull in lists of products based on specific criteria (such as brand or supplier), making the counting process more efficient.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies that the user is logged in. If not, they are redirected to the login screen.
2. Data Loading: Once authenticated, the system retrieves necessary information (such as lists of stores, product types, brands, and suppliers) to populate the dropdown menus on the form.
3. Form Entry: The user selects the store and enters the physical count for specific products. They can also use the "Autofill" tool to automatically generate a list of products to count based on filters like product type or recent movement.
4. Validation: When the user clicks "Save," the system checks that a store is selected and ensures that no counted quantities are negative.
5. Calculation: The system automatically compares the user's physical count against the current system records. It calculates the difference (variance) and the financial impact (adjustment amount) based on the product's average cost.
6. Submission: The completed data is sent to the system, a unique reference code is generated, and the user is redirected to the list of all stock opname documents.

2.3 Key Concepts

- Stock Opname: The process of physically counting inventory to verify that the actual stock matches the system records.
- Autofill Criteria: A set of filters (like brand, supplier, or product type) that helps users quickly generate a list of items to count, rather than adding them one by one.
- Variance: The difference between the physical quantity counted by the user and the quantity currently recorded in the system.
- Adjustment Amount: The financial value of the variance, calculated by multiplying the difference in quantity by the average cost of the product.
- System Quantity: The amount of stock the system currently believes is on hand before the physical count is performed.

2.4 Business Value

- Accuracy: By automating the calculation of variances and financial adjustments, the system reduces human error and ensures inventory records are precise.
- Efficiency: The autofill feature saves time by allowing users to quickly generate targeted lists of products to count, rather than manually searching for every item.
- Accountability: Every stock opname is tracked with a unique reference code and linked to specific stores, providing a clear audit trail for inventory changes.
- Financial Visibility: The system provides immediate insight into the financial impact of inventory discrepancies, helping management identify and address stock loss or reporting issues promptly.

Franchise Purchase Returns - Internal Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Franchise Purchase Return Details" feature provides a comprehensive view of a specific return transaction within the Lumi ERP system. It allows users to review the internal details, status, and itemized breakdown of a return initiated by a franchise, ensuring full visibility into the lifecycle of the document from creation to approval.

1.2 Step-by-Step Flow

1. Navigation: The user accesses the page via the Inventory module, which provides context-specific menus to ensure they remain within the correct workflow.
2. Data Retrieval: Upon loading, the system automatically fetches the full record for the selected purchase return.
3. Status Monitoring: A visual status bar displays the current stage of the return (e.g., Draft, Confirmed, Sent, or Approved), allowing the user to quickly identify where the document sits in the approval process.
4. Metadata Review: The "Details" panel presents core administrative information, such as document numbers, store/warehouse locations, and audit timestamps (created/updated by).
5. Itemized Breakdown: A detailed table lists every product included in the return, showing specific quantities (store, order, and return quantities), supply pricing, and the reason for the return.
6. Return Navigation: A dedicated back button allows the user to return to the main list of franchise purchase orders at any time.

1.3 Key Concepts

- Workflow Status: A visual indicator that tracks the progression of a document through its lifecycle, helping users understand if a return is still in progress or finalized.
- Metadata: The high-level administrative data associated with the return, such as reference numbers, involved parties (store/supplier/warehouse), and system timestamps.
- Itemized Return Data: A granular view of the products being returned, which includes specific quantity metrics and the justification for the return, providing transparency for inventory adjustments.

1.4 Business Value

- Operational Transparency: By centralizing all internal details and status updates in one view, staff can quickly verify the accuracy of a return without needing to cross-reference multiple documents.
- Improved Auditability: The inclusion of "Created By," "Updated By," and timestamp information ensures that every return has a clear trail of accountability.
- Efficient Decision Making: Providing clear visibility into return reasons and quantity discrepancies allows managers to make informed decisions regarding inventory management and franchise relations.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal Detail Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Internal Detail Page provides a centralized view for managing internal stock requests between warehouses and stores. This page allows authorized users to review the specifics of a purchase order, track its progress through the supply chain, and perform necessary actions to move the order toward completion.

1.2 Step-by-Step Flow

1. Page Loading: When you open a specific purchase order, the system automatically retrieves the order details. It verifies that the order is an "internal" franchise request before displaying the information.
2. Navigation & Status: The page displays the main navigation menu and a sub-menu set to the "Store" tab. A status bar at the top shows the current stage of the order (e.g., Draft, Confirmed, Sent, or Received).
3. Reviewing Details: The "Details" panel provides a summary of the order, including reference numbers, warehouse and store locations, key dates, and any relevant notes.
4. Itemized Breakdown: The main table lists every product included in the order, showing quantities ordered, sent, and received, along with pricing and specific remarks from both the store and the warehouse.
5. Summary Calculation: The table automatically calculates the totals for all quantities and monetary amounts at the bottom, providing an immediate overview of the order's scale.
6. Action Management: Depending on the order's current status, you can use the action buttons to edit the order, export the item list to an Excel file, or return to the main list of purchase orders.

1.3 Key Concepts

- Workflow Status: A visual tracker that shows the lifecycle of an order, ensuring users know exactly where the request stands in the fulfillment process.
- Internal Detail Panel: A summary section containing administrative information such as document codes, involved parties (warehouse/store), and important timestamps.
- Itemized Table: A detailed grid that breaks down the order by product, allowing for precise tracking of quantities and remarks for each individual item.
- Tabbed Navigation: A structure that organizes information into logical categories (Details, Invoice, and Returns), with the "Details" tab serving as the primary view.

1.4 Business Value

This feature streamlines internal inventory management by providing a single source of truth for franchise purchase orders. By clearly displaying the status and itemized details of each order, it reduces communication errors between warehouses and stores, ensures accurate tracking of stock movement, and simplifies the review process for store managers and warehouse staff. The ability to export data and easily navigate between order states helps maintain operational efficiency and accountability.

2. Logic

2.1 Overview

The Franchise Purchase Order Internal Detail page provides a comprehensive view of specific internal stock orders. It allows users to review order details, track the current progress of the order through its lifecycle, and manage the items associated with that order. This page ensures that all relevant information—from supplier details to specific product quantities—is centralized for easy verification and management.

2.2 Step-by-Step Flow

1. Page Initialization: When a user selects a specific purchase order, the system retrieves the order details.
2. Validation: The system checks that the selected order is categorized as an "internal" franchise order. If it is not, the system will not display the details.
3. Data Mapping: Once validated, the system organizes the information into three main areas:

* Header Panel: Displays administrative details such as document numbers, warehouse/store locations, dates, and notes.

* Workflow Status: Shows the current stage of the order (e.g., Draft, Confirmed, Sent, or Received).

* Items Table: Lists every product in the order, including quantities (ordered, sent, and received), pricing, and any specific remarks from the store or warehouse.

4. Summary Calculation: The system automatically calculates totals for quantities and monetary amounts based on the items listed in the table to provide a quick overview of the order's scale.

2.3 Key Concepts

– Internal Purchase Order: A specific type of stock request used for moving inventory between internal franchise locations or warehouses.
– Workflow State: The current phase of the order, which guides the user on what actions (such as confirming, sending, or receiving) are available next.
– Header Panel: The top section of the page containing metadata, such as reference codes, timestamps, and the parties involved in the transaction.

- Items Table: A detailed breakdown of the products, showing the lifecycle of each item from the initial order quantity to the final received amount.
- Supply Price (Inc. Tax): The cost of the product per unit, including all applicable taxes, used to calculate the total order value.

2.4 Business Value

This feature streamlines inventory management by providing a single source of truth for internal franchise orders. By automating the calculation of totals and clearly displaying the workflow status, it reduces manual errors and helps staff quickly identify the status of their stock. This transparency ensures that both the warehouse and the store are aligned on what has been ordered, sent, and received, ultimately leading to more efficient stock replenishment and better operational oversight.

3. Data

3.1 Overview

The Franchise Purchase Order Internal Detail page provides a comprehensive view of a specific purchase order within the Lumi ERP system. This page is designed to give internal staff full visibility into the lifecycle of an order—from the initial request and warehouse fulfillment to the final receipt at the store. It consolidates administrative details, current workflow status, and a detailed breakdown of products, quantities, and financial totals.

3.2 Step-by-Step Flow

1. Data Retrieval: The system fetches the complete details for a specific purchase order, including header information, status, and a list of all items involved.
2. Header Display: The page populates the top section with key administrative data, such as document numbers, warehouse and store locations, supplier information, and important dates (creation, due date, and fulfillment timestamps).
3. Workflow Status: The system displays the current stage of the order (e.g., pending, sent, or received) to ensure staff understand the order's progress.
4. Itemized Breakdown: The system lists every product in the order, showing specific details like the SKU, product name, and individual quantities for items ordered, sent, and received.
5. Financial Summary: The system automatically calculates and displays the totals at the bottom of the item table, providing a clear view of the total quantities and monetary values for the entire order.

3.3 Key Concepts

- Workflow State: The current phase of the purchase order, which helps track whether the order is still being processed, has been shipped, or has been completed.
- Header Details: The high-level metadata of the order, including reference codes, responsible parties, and relevant dates that define the order's context.
- Itemized Quantities: A three-way comparison of product counts (Ordered vs. Sent vs. Received) that allows staff to identify discrepancies between what was requested and what was actually delivered.
- Tax-Inclusive Pricing: Financial values displayed on the page include applicable taxes, ensuring that the "Order," "Sent," and "Receive" amounts reflect the actual cost.
- Summary Totals: Aggregated calculations at the bottom of the item list that provide an immediate snapshot of the total volume and financial value of the purchase order.

3.4 Business Value

This feature centralizes all critical information regarding a franchise purchase order into a single, easy-to-read interface. By providing a clear comparison between ordered, sent, and received quantities, it enables staff to quickly identify fulfillment gaps or errors. The automated summary totals reduce the need for manual calculations, improving operational efficiency and ensuring that internal teams have the accurate, real-time data needed to manage inventory and supplier relationships effectively.

Store - New Discrepancy Stocks Report

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Discrepancy Stocks Report" feature provides a dedicated page within the Inventory module for staff to record stock discrepancies. This tool allows users to select a specific store, identify products with stock mismatches, specify the quantity involved, and add explanatory notes. The system ensures data integrity by validating entries before saving them as a new "Draft" report.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system verifies the user's login status and automatically populates the "Entity" dropdown with a list of available stores.
2. Adding Items: The page starts with one empty row. Users can add more rows as needed by clicking the "Add Item" button.
3. Product Selection: Within each row, users search for products by typing their name, SKU, or code. The system provides real-time search results to ensure the correct item is selected.
4. Data Entry: For each selected product, the user enters the discrepancy quantity (which must be greater than zero) and any relevant notes.
5. Managing Rows: If a user adds a row by mistake, they can remove it using the delete icon.
6. Saving: Once the form is complete, the user clicks "Save." The system validates that a store is selected, all rows have valid products and quantities, and no duplicate products are listed.
7. Completion: Upon successful validation, the report is saved as a "Draft" and the user is redirected back to the main list of discrepancy reports. If validation fails, the system highlights the errors so the user can correct them.

1.3 Key Concepts

- Entity: The specific store location where the stock discrepancy is being reported.
- Discrepancy: A mismatch between the recorded stock levels and the actual physical count.
- Draft Status: The initial state of a new report, allowing for review before any final stock adjustments are processed.
- Validation: Automated checks that prevent incomplete or incorrect data (such as zero quantities or missing product selections) from being saved.

1.4 Business Value

-

Accuracy: By requiring specific product identification and quantity entry, the feature reduces manual errors in inventory tracking.

- Accountability: The inclusion of notes for each discrepancy provides a clear audit trail, helping management understand why stock levels were adjusted.
- Efficiency: The streamlined, row-based interface allows staff to quickly document multiple discrepancies in a single session, saving time compared to manual or paper-based reporting.
- Standardization: By forcing all discrepancy reports through a structured digital form, the business ensures consistent data collection across all store locations.

2. Logic

2.1 Overview

The "New Discrepancy Stocks Report" feature provides a streamlined way for users to document inventory discrepancies within the Lumi ERP system. This page allows staff to select a store and list specific products that have stock variances, along with the quantity and any relevant notes. The system automatically handles administrative details like document numbering and status tracking, ensuring that records are created consistently and accurately.

2.2 Step-by-Step Flow

1. Authentication & Setup: When the page loads, the system verifies the user's login status. If authorized, it automatically retrieves a list of active stores to populate the "Select Entity" dropdown.
2. Adding Items: Users can add products to the report. As the user types a product name, SKU, or code, the system searches the product database in real-time to help the user select the correct item.
3. Data Entry: For each selected product, the user enters the discrepancy quantity and any necessary notes. Users can add multiple rows or remove rows as needed.
4. Saving the Report: Once the form is complete, the user clicks "Save." The system validates the input (e.g., ensuring a store is selected and the table is not empty) and submits the data.
5. System Processing: Upon a successful save, the server automatically assigns a unique document reference code, sets the status to "Draft," and records the creation date.
6. Completion: The user is redirected back to the main Discrepancy Stocks list, where the new report appears at the top of the list. If there are any errors during saving, the system highlights the specific fields that need attention.

2.3 Key Concepts

- Discrepancy Stock: A record used to track differences between expected and actual inventory levels.
- Entity Field: A selection menu that allows the user to specify which store location the inventory discrepancy belongs to.
- Draft Status: The initial state of a new report, indicating that it has been created but is still open for review or further action.
- Document Reference Code: A unique, system-generated identifier (e.g., DISC/StoreCode/Sequence) that makes it easy to track and find specific reports.
- Validation: Automated checks performed by the system to prevent incomplete or incorrect data from being saved, such as preventing duplicate product entries or zero-quantity reports.

2.4 Business Value

This feature simplifies inventory management by providing a dedicated, user-friendly interface for reporting stock variances. By automating the generation of reference codes and document statuses, the system reduces manual administrative work and minimizes the risk of human error. This ensures that inventory discrepancies are captured in a standardized format, allowing for better oversight and more accurate stock reconciliation across all store locations.

3. Data

3.1 Overview

The "New Discrepancy Stocks Report" feature allows store staff to formally document inventory mismatches within the Lumi ERP system. When a user identifies a difference between expected and actual stock levels, they can create a "Discrepancy Stock" record. This feature ensures that these findings are captured accurately, assigned a unique tracking number, and saved as a draft for further review or processing.

3.2 Step-by-Step Flow

1. Data Entry: The user selects the relevant store location and adds one or more products to the report, specifying the quantity of the discrepancy and any necessary notes for each item.
2. Validation: The system checks the entry to ensure a store is selected, the product list is not empty, no duplicate products are listed, and all quantities are greater than zero. If any information is missing or incorrect, the system alerts the user and keeps the form open for corrections.
3. Document Generation: Once validated, the system automatically generates a unique reference code for the report based on the store location and a sequential number.
4.

Record Creation: The system saves the report header and the list of items as a single "Draft" record. No changes are made to actual inventory levels at this stage, as this is a documentation step.

5. Confirmation: Upon successful saving, the user is redirected to the main Discrepancy Stocks list, where the new report appears at the top with its unique reference code and a "Draft" status.

3.3 Key Concepts

- Discrepancy Stock: A formal record used to document items where the physical count does not match the system records.
- Draft Status: The initial state of a report, indicating that it has been saved but has not yet triggered any final inventory adjustments.
- Document Reference: A unique, system-generated identifier (e.g., DISC/STORE-CODE/0001) that allows staff to easily track and locate specific discrepancy reports.
- Validation: Automated checks that prevent incomplete or erroneous data from being saved, ensuring the integrity of the inventory records.

3.4 Business Value

This feature provides a structured and reliable way to track inventory errors. By moving from informal notes to a standardized digital report, the business gains better visibility into stock inaccuracies. Because the system handles the unique numbering and validation, it reduces manual data entry errors and ensures that all discrepancies are accounted for before any final inventory adjustments are made.

BUSINESS REQUIREMENTS DOCUMENT

Store - New Stock Transfer

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Stock Transfer" feature provides a dedicated page within the Inventory module to initiate the movement of goods between two locations. This page allows users to create a draft transfer request, specify the source and destination stores, select the products to be moved, and define the quantities. The system provides real-time visibility into current stock levels and costs to ensure accuracy before the transfer is finalized.

1.2 Step-by-Step Flow

1. Initialization: Upon opening the page, the system verifies your login status and automatically populates the location lists. The transfer type defaults to "Sent."
2. Header Setup: You select the source location (where goods are leaving) and the destination location (where goods are arriving). You may also add an optional reference code, due date, and notes.
3. Adding Products: You add products to the transfer list. As you search for items, the system automatically displays the current stock levels at both the source and destination, along with the average cost at the source location.
4. Defining Quantities: For each product, you enter the specific quantity you wish to transfer. The system automatically calculates the total cost for that line item and updates the overall transfer cost.
5. Bulk Upload (Optional): If you have a large list of items, you can use the Upload Manager to import products and quantities from a file instead of adding them manually.
6. Validation & Saving: Once the form is complete, you click "Save." The system validates that the locations are different, the product list is not empty, and all transfer quantities are greater than zero. If valid, the transfer is created as a "Draft" and you are redirected to the document's detail page.

1.3 Key Concepts

- Source/Destination Locations: The specific stores or warehouses involved in the movement of stock.
- Stock Snapshot: Real-time data showing how much of a product is currently available at a location, provided to help you make informed transfer decisions.
- Transfer Quantity: The specific number of units you intend to move; this is the primary input required for each product line.
- Draft Status: The initial state of a new transfer document, indicating it has been created but not yet processed or approved.
-

Average Cost: The unit cost of a product at the source location, used to calculate the total financial value of the items being transferred.

1.4 Business Value

This feature streamlines inventory management by providing a controlled, error-resistant way to move stock. By requiring users to select valid locations and providing real-time visibility into stock levels and costs, the system prevents common errors—such as transferring items that aren't in stock or selecting the same location for both ends of the transfer. The ability to save as a "Draft" allows for flexible workflows, ensuring that documentation can be prepared and reviewed before the physical movement of goods is officially confirmed.

2. Logic

2.1 Overview

The "New Stock Transfer" feature provides a dedicated page for users to initiate the movement of inventory between two locations. This page ensures that stock transfers are accurately recorded, validated, and tracked from the moment they are created as a draft.

2.2 Step-by-Step Flow

1. Authentication & Setup: When the page loads, the system verifies the user is logged in. It then populates the "From" and "To" location dropdowns and sets default values for the transfer type, leaving other fields blank.
2. Adding Products: Users can add items to the transfer by searching for products. The search is restricted to the selected "From" location to ensure accurate inventory data.
3. Real-time Guidance: As products are added, the system displays the current stock levels at both the source and destination, along with the average cost at the source. These figures act as a reference for the user.
4. Quantity Adjustments: As the user enters the quantity to be transferred, the system automatically calculates the total cost for that line item and updates the overall total cost for the entire transfer.
5. Submission: Once the user clicks "Save," the system validates the request (e.g., ensuring the source and destination are different and the table is not empty).
6. Completion: Upon successful validation, the transfer is created as a "Draft," and the user is automatically redirected to the new document's detail page.

2.3 Key Concepts

- Source Location: The warehouse or store from which the inventory is being moved.
- Destination Location: The warehouse or store receiving the inventory.
-

Product Lookup: A search tool that helps users find items and provides a snapshot of current stock levels and costs to assist in decision-making.

- Draft Status: The initial state of a stock transfer document, indicating it has been created but not yet finalized or processed.
- Validation: Automated checks performed by the system to prevent errors, such as selecting the same location for both "From" and "To" or submitting an empty transfer.

2.4 Business Value

This feature streamlines inventory management by providing a controlled, error-resistant process for moving stock. By automating cost calculations and providing real-time visibility into stock levels at both locations, it reduces manual data entry errors and ensures that inventory records remain accurate and consistent across the organization.

3. Data

3.1 Overview

The "New Stock Transfer" feature allows users to move inventory items between different locations within the Lumi ERP system. This page provides a structured way to document which products are being moved, the quantity involved, and the origin and destination points. When a transfer is saved, the system automatically records the transaction details and captures the current cost of the items to ensure accurate financial tracking.

3.2 Step-by-Step Flow

1. Data Entry: The user fills out the transfer header (source location, destination location, date, reference number, and notes) and adds items to the product table, specifying the product and the quantity to be moved.
2. Validation: When the user clicks "Save," the system checks for errors. It ensures the source and destination locations are different, that at least one item is included, and that all transfer quantities are greater than zero.
3. Processing: If valid, the system creates a new "Draft" transfer record. It automatically looks up the current cost of each product and saves that price as a permanent "snapshot" for this specific transfer.
4. Confirmation: Once the data is successfully saved, the system redirects the user to the newly created transfer document, where they can review the details in its initial "Draft" status.
5. Error Handling: If any validation rules are not met, the system stops the process, keeps the form open, and displays a message explaining why the transfer could not be saved.

3.3 Key Concepts

-

Stock Transfer: A formal record of moving specific quantities of products from one designated location to another.

- Draft Status: The initial state of a new transfer, allowing users to review or edit the information before it is finalized or processed.
- Snapshot Cost: A record of the product's cost at the exact moment the transfer is created, which preserves financial accuracy even if the product's market price changes later.
- Validation Rules: Automated checks that prevent common errors, such as trying to transfer items to the same location they are already in or submitting a transfer with no items.

3.4 Business Value

This feature streamlines inventory management by providing a reliable, auditable trail for all stock movements. By automating the capture of product costs at the time of transfer, the system reduces manual data entry errors and ensures that financial reporting remains accurate. The "Draft" workflow provides a safety net, allowing staff to verify transfer details before they officially impact inventory levels.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Order Details Pages

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Order Details page provides a centralized view for managing inventory requests within the Lumi ERP system. This page allows users to view specific order information, track the progress of an order through its lifecycle, and perform necessary actions—such as confirming, reviewing, or receiving stock—based on the order's current status.

1.2 Step-by-Step Flow

1. Page Initialization: When the page loads, the system automatically retrieves the order’s core details and the list of items associated with that order.
2. Displaying Information: The page displays the order metadata (such as reference numbers and warehouse details) in a dedicated panel, while individual products are listed in a sortable table.
3. Sorting Data: Users can click on column headers (such as SKU, Product, or Order Quantity) to sort the list of items in ascending or descending order to help locate specific information quickly.
4. Workflow Progression: Depending on the current status of the order (e.g., Draft, Store Confirmed, or Warehouse Sent), the system displays relevant action buttons.
5. Action Execution: When a user clicks an action button (like "Confirm"), a confirmation window appears to prevent accidental changes. Once confirmed, the system updates the order status and moves it to the next stage of the workflow.

1.3 Key Concepts

- Workflow Status Bar: A visual tracker that shows the current stage of the order (e.g., Draft, Store Confirmed, Warehouse Sent, or Store Received) to ensure users know exactly where the order stands in the process.
- Details Panel: A summary section that provides essential context about the order, including source information, dates, and administrative notes.
- Sortable Table: A data grid that allows users to organize product information by clicking on headers, making it easier to manage large lists of items.
- Action Buttons: Context-aware controls that only appear when they are relevant to the current order status, ensuring users only perform valid operations at the right time.

1.4 Business Value

This feature streamlines inventory management by providing a clear, guided process for handling stock orders. By automating the status tracking and providing a consistent interface for reviewing and confirming orders, the

system reduces manual errors, improves communication between the store and the warehouse, and ensures that inventory records remain accurate throughout the entire fulfillment lifecycle.

2. Logic

2.1 Overview

The Stock Order Details page provides a centralized view for managing inventory requests. It allows users to view specific order information, review the list of requested products, and perform final actions such as confirming or cancelling an order.

2.2 Step-by-Step Flow

1. Page Initialization: When a user opens a specific stock order, the system simultaneously retrieves the order's header information (such as the warehouse location and status) and the list of individual items included in that order.
2. Data Display: The system populates the page header with the order details and fills the product table with the retrieved items, ensuring that information like product codes, quantities, and costs are clearly mapped to their respective columns.
3. Order Confirmation: If the user chooses to confirm the order, the system updates the order status to "Confirmed" to reflect that the request is finalized.
4. Order Cancellation: If the user chooses to cancel, the system prompts for a final confirmation to prevent accidental clicks. Once confirmed, the order status is updated to "Cancelled."

2.3 Key Concepts

- Stock Order Header: The top-level information for an order, including the unique order ID, current status, creation date, and the associated warehouse.
- Line Items: The specific products requested within an order, displayed in a table format that includes details like SKU, product name, quantity, and average cost.
- Status Transition: The process of changing an order's state (e.g., from "Pending" to "Confirmed" or "Cancelled") to ensure the system accurately reflects the current progress of the inventory request.
- Data Mapping: The process of taking raw system information and organizing it into the user-friendly table columns (such as "Order Qty" or "Store Remark") for easier reading.

2.4 Business Value

This feature streamlines inventory management by providing a clear, organized interface for staff to verify and process stock requests. By separating the order header from the item list, users can quickly assess the scope

of an order, while the built-in confirmation steps for status changes help reduce errors and ensure that inventory records remain accurate and reliable.

3. Data

3.1 Overview

The Stock Order Details page provides a centralized view for managing individual stock orders within the Lumi ERP system. This feature allows users to view comprehensive order information, including specific product line items, and provides the necessary controls to finalize or cancel an order directly from the interface.

3.2 Step-by-Step Flow

1. Page Initialization: When a user opens a specific stock order, the system verifies their access permissions.
2. Data Retrieval: The system simultaneously fetches the main order details (such as the warehouse location and status) and the list of products associated with that order.
3. Display: The product list is organized into a clear table format, showing details like product codes, quantities, average costs, and any specific remarks added by the store.
4. Workflow Management:

* Confirming: If the user chooses to confirm the order, the system updates the order status to "Confirmed."

* Canceling: If the user chooses to cancel, the system reverts the order to a "Cancelled" state and refreshes the page to reflect the updated status.

3.3 Key Concepts

- Stock Order: The primary document representing a request for inventory, containing header information like the warehouse destination and current status.
- Line Items: The individual rows within a stock order that detail specific products, including their quantities, costs, and any store-specific notes.
- Workflow Status: The current stage of an order (e.g., Pending, Confirmed, or Cancelled), which dictates what actions a user can take.
- Pagination: A method used to display large lists of products in manageable chunks, ensuring the page remains fast and easy to read.

3.4 Business Value

- Operational Efficiency: By consolidating order headers and line items into a single view, staff can quickly verify order accuracy without navigating between multiple screens.
-

Improved Accuracy: Standardized mapping of product data ensures that store staff see consistent information, such as product codes and average costs, reducing the risk of manual entry errors.

- Streamlined Decision Making: Providing clear "Confirm" and "Cancel" actions directly on the details page allows for faster processing of inventory requests, helping to keep warehouse operations moving smoothly.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Stock Order Warehouse

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Stock Order Warehouse" page is a dedicated interface within the Lumi ERP system designed to help staff create and manage requests for moving stock from a warehouse to a specific store. This feature streamlines the ordering process by allowing users to input order details, select products, and specify quantities in a single, organized workflow.

1.2 Step-by-Step Flow

1. Navigation: The user accesses the page via the main menu by selecting the "Inventory" module and ensuring the "Store" tab is active.
2. Order Details Entry: The user fills out the primary order information, including the source warehouse, the destination store, a reference code, the requested delivery date, and any additional notes.
3. Product Selection: The user adds products to the order. For each product, they specify the current store quantity, the amount they wish to order, and any relevant remarks. The system automatically displays the company’s average cost for each item.
4. Submission: Once the form is complete, the user clicks "Save." The system validates the information and submits the order to the inventory database.
5. Completion: Upon a successful save, the user is automatically redirected back to the main Stock Order List page.
6. Cancellation: If the user decides not to proceed, they can click "Cancel" at any time to discard their changes and return to the Stock Order List page.

1.3 Key Concepts

- Stock Order: A formal request to transfer inventory items from a central warehouse to a retail store location.
- Workflow State: The current status of the order; new orders begin as a "draft" until they are finalized and submitted.
- Reference Code: A unique identifier or tracking number assigned to the order for easy searching and record-keeping.
- Company Average Cost: A read-only value provided by the system that shows the standard cost of an item, helping users understand the financial impact of the order.

1.4 Business Value

-

Operational Efficiency: By centralizing the order entry process, staff can quickly generate stock requests without navigating multiple screens.

- Data Accuracy: Standardized forms and required fields ensure that all necessary information—such as delivery dates and specific quantities—is captured correctly before an order is processed.
- Improved Inventory Control: Providing visibility into current store quantities and average costs allows for more informed decision-making, helping to prevent overstocking or stockouts at the store level.

2. Logic

2.1 Overview

The "New Stock Order Warehouse" feature allows users to create and submit requests to move inventory from a central warehouse to a specific store. This feature streamlines the ordering process by capturing all necessary logistical details—such as the source warehouse, destination store, delivery deadlines, and specific product quantities—into a single, organized digital order.

2.2 Step-by-Step Flow

1. Data Entry: The user fills out the "New Order Warehouse" form with general information, such as the source warehouse, destination store, reference codes, due dates, and any relevant notes.
2. Product Selection: The user adds specific items to the order, detailing the product, the quantity currently held at the store, the quantity being ordered, and any specific remarks for each item.
3. Submission: Once the user clicks the "Save" button, the system automatically gathers all the information from the form and the product list.
4. Validation and Processing: The system checks the data to ensure it meets all requirements. If valid, it saves the order to the system.
5. Confirmation: Upon a successful save, the user is automatically redirected to the main Stock Order List page to view the status of their newly created order.

2.3 Key Concepts

- Stock Order Header: The primary information for the request, including the "who, where, and when" (e.g., source warehouse, destination store, and due date).
- Line Items: The specific list of products included in the order, along with their respective quantities and costs.
- Workflow State: The current status of the order within the system (e.g., draft, pending, or approved).
- Reference Code: A unique identifier or document number used to track the order for easy searching and auditing.

2.4 Business Value

- Operational Efficiency: By centralizing the ordering process, staff can quickly request stock without manual paperwork, reducing the time spent on administrative tasks.
- Accuracy: Standardized forms ensure that all necessary information—such as product quantities and delivery deadlines—is captured correctly before an order is processed, minimizing errors.
- Improved Inventory Visibility: Because the system tracks the movement of goods from the warehouse to the store, managers gain better insight into stock levels and replenishment needs across all locations.

3. Data

3.1 Overview

The New Stock Order Warehouse feature allows users to create and submit a formal request to move inventory from a central warehouse to a specific store. This process captures all necessary details—such as which products are needed, the quantities required, and the expected delivery timeline—ensuring that inventory replenishment is tracked accurately within the Lumi ERP system.

3.2 Step-by-Step Flow

1. Initiation: The system begins the process of recording a new stock order request.
2. Order Header Creation: The system saves the primary order information, including the source warehouse, the destination store, a unique reference code, the requested due date, and any additional notes.
3. Itemized Entry: The system processes the list of products included in the order. For each product, it records the specific quantity requested, the current stock level at the store, the average cost of the item, and any specific remarks provided by the store.
4. Finalization: Once all items are successfully recorded, the system confirms the order, making it available for fulfillment.

3.3 Key Concepts

- Stock Order: A formal document that tracks the movement of goods from a warehouse to a retail store.
- Warehouse: The central storage location where inventory is held before being distributed to stores.
- Store: The retail location receiving the inventory.
- Line Item: An individual entry within a stock order that specifies a particular product and the quantity requested for that item.
-

Reference Code: A unique identifier assigned to each order to make it easy to search for and track throughout the fulfillment process.

3.4 Business Value

This feature streamlines the replenishment process by providing a standardized way for stores to request stock. By capturing both the requested quantity and the store's current stock levels, the system enables better inventory visibility and data-driven decision-making. This reduces manual errors, ensures that warehouses have clear instructions for picking and packing, and helps maintain optimal stock levels across all retail locations.

BUSINESS REQUIREMENTS DOCUMENT

Company - New Purchase Return

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Purchase Return" feature provides a streamlined way for users to process returns for items previously purchased by the company. By selecting an existing invoice, the system automatically pulls in the relevant order details, allowing users to specify the quantity to be returned and the reason for the return. The system handles all financial calculations—such as subtotals, taxes, and discounts—automatically to ensure accuracy before the return is finalized.

1.2 Step-by-Step Flow

1. Initiate Return: The user selects the "Return" type from the required dropdown menu.
2. Select Supplier and Invoice: The user chooses a supplier, then searches for the specific invoice (requiring at least 3 characters).
3. Auto-fill Details: Once the invoice is selected, the system automatically populates the associated Purchase Order, Purchase Delivery reference, and the list of items included in that original purchase.
4. Adjust Quantities and Reasons: For each item in the list, the user enters the quantity to be returned (which cannot exceed the original amount purchased) and provides a reason for the return.
5. Review Financials: The system calculates the subtotal, applies any entered discounts (automatically formatted for consistency), and adds the applicable tax to display a final total.
6. Save and Finalize: Upon clicking "Save," the system validates all entries and submits the data. If successful, the user is redirected to the Purchase Return list page.

1.3 Key Concepts

- Invoice Search: A security and efficiency measure that requires a minimum of 3 characters to find an invoice, ensuring the user selects the correct document linked to a specific supplier.
- Auto-fill Logic: The system automatically retrieves and displays related data (like Purchase Orders and Delivery references) based on the invoice selection to reduce manual data entry and errors.
- Validation Rules: Built-in checks that prevent invalid data, such as ensuring return quantities do not exceed the original invoice amounts.
- Dynamic Calculations: The system continuously updates the financial summary (subtotal, tax, and total) as items are added, removed, or quantities are adjusted.
- Data Formatting: Automatic adjustment of discount entries to ensure financial records remain consistent and professional.

1.4 Business Value

This feature reduces manual administrative work and minimizes human error by automating the retrieval of purchase history and financial calculations. By enforcing strict validation on return quantities and requiring specific reasons for returns, the company maintains better inventory accuracy and clearer audit trails for all returned goods. This leads to faster processing times and more reliable reporting for the inventory management team.

2. Logic

2.1 Overview

The "New Purchase Return" feature allows users to formally record the return of items to a supplier. This process ensures that inventory records are updated accurately and financial adjustments—such as subtotals, discounts, and taxes—are calculated automatically based on the items being returned.

2.2 Step-by-Step Flow

1. Form Initialization: The user begins by selecting the supplier and the specific invoice associated with the return. The system automatically populates related details like the Purchase Order and delivery information.
2. Item Selection: The system displays the products from the selected invoice. The user specifies the quantity to be returned for each item and provides a reason for the return.
3. Automatic Calculation: As the user enters quantities and applies any discounts, the system instantly calculates the subtotal, tax, and final total for the return document.
4. Validation: Before submission, the system ensures all mandatory information (such as the return type, supplier, and invoice) is present.
5. Submission: Once the user clicks the save button, the system processes the return, saves the data, and redirects the user to the main list of purchase returns.

2.3 Key Concepts

- Purchase Return: A formal document used to track goods sent back to a supplier, ensuring the company's inventory and financial records remain in sync.
- Invoice Linking: By selecting an existing invoice, the system pulls in pre-verified product data and pricing, reducing manual entry errors.
- Automated Financials: The system handles the math for subtotals, tax applications, and discounts, ensuring the final return value is always accurate.
- Return Reason: A required field for each item that provides auditability and insight into why goods are being returned (e.g., damaged, incorrect item).

2.4 Business Value

- Accuracy: Automating the calculation of totals and taxes eliminates manual math errors.
- Efficiency: Linking returns to existing invoices saves time by auto-filling product details and purchase order information.
- Audit Readiness: By requiring reasons for returns and maintaining a clear link to original invoices, the business maintains a transparent and reliable audit trail for all inventory adjustments.

3. Data

3.1 Overview

The "New Purchase Return" feature allows your team to formally record the return of goods to a supplier. This process is integrated with your existing invoice system, ensuring that return records are accurate, linked to original purchase documents, and validated against previous transactions to prevent errors.

3.2 Step-by-Step Flow

1. Initiation: You select an existing invoice to start the return process. The system automatically pulls in relevant details, such as the associated purchase order, delivery information, and the list of products from that invoice.
2. Data Entry: You fill out the return form, including the supplier, the warehouse where the goods are being returned from, and any optional reference numbers or notes.
3. Item Selection & Validation: You specify the quantity of each product being returned and provide a reason for the return. The system automatically checks that the return quantity does not exceed the amount originally purchased on the invoice.
4. Financial Calculation: The system automatically calculates the subtotal, applies any discounts, adds the appropriate tax, and displays the final total for the return.
5. Submission: Once submitted, the system generates a unique document number for the return and saves the record, linking it to the original invoice and purchase order for full traceability.

3.3 Key Concepts

- Invoice Linking: Every return is tied to a specific invoice, which ensures that the return is based on verified historical data.
- Quantity Validation: A built-in safeguard that prevents users from returning more items than were originally received, maintaining inventory integrity.
- Automated Calculations: The system handles the math for subtotals, taxes, and discounts, reducing the risk of manual entry errors.

- Traceability: By generating a unique document number and linking to the original purchase order, the system creates a clear audit trail for every return.

3.4 Business Value

- Accuracy: By auto-populating data from invoices and validating quantities, the feature eliminates manual data entry errors and prevents over-returning of stock.
- Efficiency: Staff spend less time manually calculating totals or looking up purchase details, as the system handles these tasks automatically.
- Compliance & Auditability: Maintaining a formal, linked record of all returns ensures your inventory and financial reporting remain transparent and easy to audit.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Return (Standard) Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Purchase Return (Standard) Details page provides a comprehensive view of a specific return transaction. It allows users to track the status of a return, review itemized details, and manage the workflow from the initial draft stage through to final approval by the supplier.

1.2 Step-by-Step Flow

1. Data Loading: When you open the page, the system automatically retrieves all relevant details for the selected purchase return. A loading indicator is displayed while this data is being fetched.
2. Reviewing Information: The page displays key information, including the document number, status, general reference details, linked documents (such as Purchase Orders or Invoices), and audit logs (who created or updated the record).
3. Workflow Management:

* Draft Stage: You can edit the document, print it, or send it to the supplier.

* Sent to Supplier Stage: Once sent, you can print the document or begin the approval process.

* Approval Process: Clicking "Approve" triggers a confirmation modal. You will then review the quantities and enter the amounts confirmed by the supplier.

* Finalization: After entering the supplier-confirmed quantities, a final approval step saves the data, moving the document to the "Approved" status.

4. Itemized Summary: The page includes a table listing all returned items, showing quantities (remaining, warehouse, returned, and confirmed), pricing, and the reason for the return. A summary section at the bottom provides totals for these quantities and financial data.

1.3 Key Concepts

- Workflow Status: A tracker that shows the current stage of the return (Draft, Sent to Supplier, or Approved).
- Supplier Confirmed Quantity: An editable field used during the approval process to record the exact quantity the supplier has agreed to accept as a return.
- Linked Documents: Direct links to related records, such as the original Purchase Order, Purchase Delivery, or Invoice, allowing for easy navigation between related transactions.
- Audit Trail: A section displaying timestamps and user information for when the document was created, updated, sent, or approved.
-

Financial Summary: A breakdown of the return's value, including subtotals, discounts, taxes, and any allocated credit amounts.

1.4 Business Value

This feature centralizes the management of purchase returns, ensuring that all stakeholders have a clear, real-time view of the return status. By enforcing a structured workflow—from drafting to supplier confirmation—the system reduces manual errors, improves inventory accuracy, and provides a transparent audit trail for financial reconciliation.

2. Logic

2.1 Overview

The Purchase Return (Standard) detail page provides a comprehensive view of items being returned to a supplier. This feature allows users to review return documentation, track the status of the return process, and manage the workflow from the initial draft through to final approval. It ensures that all financial data, inventory quantities, and audit information are clearly visible and organized for easy verification.

2.2 Step-by-Step Flow

1. Page Loading: When you open a specific Purchase Return record, the system automatically retrieves all relevant details, including the document numbers, associated purchase orders, invoices, and the list of items being returned.
2. Data Aggregation: The system calculates the totals for various quantity categories (such as "Return," "Warehouse," and "Confirmed" quantities) to provide a summary row at the bottom of the item list.
3. Reviewing Details: You can view financial summaries (subtotals, taxes, and discounts), audit logs (who created or updated the record), and links to related documents like journals or payments.
4. Sending to Supplier: Once the return is ready, you can trigger the "Send to Supplier" action. This updates the document status and records the exact time it was sent.
5. Approval: After the supplier confirms the return, you can use the approval function to finalize the record. This updates the status to "Approved/Confirmed" and logs the approval date.

2.3 Key Concepts

- Purchase Return: A formal document used to track goods being sent back to a supplier, including the reason for the return and the quantities involved.
- Workflow Status: The current stage of the return process, which moves from "Draft" to "Sent to Supplier" and finally to "Approved/Confirmed."

- Quantity Tracking: A breakdown of item counts, including what is currently in the warehouse, what is being returned, and what the supplier has officially confirmed.
- Financial Summary: A clear view of the monetary impact of the return, including subtotals, discounts, taxes, and any allocated credit amounts.
- Audit Trail: Automatically captured information regarding who created or modified the record and when key actions (like sending or approving) occurred.

2.4 Business Value

This feature centralizes the entire return process, reducing manual errors by automatically calculating totals and linking related financial documents. By providing a clear, step-by-step workflow, it ensures that inventory records remain accurate and that there is full transparency between the company and the supplier regarding returned goods and credit adjustments.

3. Data

3.1 Overview

The Purchase Return (Standard) detail page provides a comprehensive view of a return transaction initiated with a supplier. This feature allows users to see the full lifecycle of a return—from the initial request and financial breakdown to the final approval status. It acts as a central hub for tracking returned items, associated invoices, payments, and warehouse movements, ensuring that all inventory and accounting records remain accurate.

3.2 Step-by-Step Flow

1. Record Retrieval: When a user selects a specific purchase return, the system gathers all relevant data, including the primary document details, linked financial records (like invoices and payments), and the list of items being returned.
2. Itemized Breakdown: The system displays a detailed table of all returned products, showing quantities (such as what was returned versus what the supplier confirmed), pricing, and the specific reason for each return.
3. Summary Calculation: The system automatically calculates and displays totals for all quantity columns and financial fields (subtotal, tax, discounts, and final total) to provide an immediate snapshot of the return's value.
4. Workflow Tracking: The system displays the current status of the return (e.g., Draft, Sent to Supplier, or Approved) along with key audit timestamps, such as when the document was created, sent, or approved.
5. Approval View: For management purposes, the system provides a simplified view that highlights only the essential information—such as the document number, total value, and approval status—to facilitate quick review and authorization.

3.3 Key Concepts

- Purchase Return: A formal record documenting the return of goods to a supplier, which often triggers adjustments to inventory levels and financial accounts.
- Workflow Status: The current stage of the return process, which helps users understand if a document is still being drafted, has been sent to the supplier, or has been finalized.
- Audit Trail: A collection of timestamps and user identifiers that track who created or updated the record and when key actions (like approval) occurred.
- Linked Documentation: References to related records, such as the original Purchase Order, the Invoice, and the specific Warehouse involved, allowing users to navigate easily between related business documents.

3.4 Business Value

This feature improves operational transparency and financial accuracy by centralizing all data related to a return. By providing a clear view of both item quantities and financial totals, it reduces the risk of discrepancies between warehouse records and accounting books. Furthermore, the integrated workflow and audit trail ensure that every return is properly authorized and tracked, helping the business maintain strong relationships with suppliers and clear accountability for inventory adjustments.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Orders (Fixed Asset)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Purchase Orders (Fixed Asset)" feature provides a dedicated workspace within the Inventory module for managing purchase orders specifically related to fixed assets. This page allows users to view, search, and filter these orders in a structured table format, ensuring that asset-related procurement is tracked separately from general inventory.

1.2 Step-by-Step Flow

1. Accessing the Page: Users navigate to the Inventory section and select the "Fixed Asset" tab to view the relevant purchase orders.
2. Automatic Data Loading: Upon opening the page, the system automatically retrieves all purchase orders categorized as fixed assets.
3. Filtering and Searching: Users can refine the list using the toolbar, which includes search text, status selection, and date range pickers. The list updates only after the user clicks the search button.
4. Viewing Details: The table displays key information for each order, including document numbers, supplier details, status, financial totals, and counts for deliveries, invoices, and returns.
5. Navigation: Users can browse through the list using the pagination controls, which display 20 records at a time.
6. Creating New Orders: A dedicated button is available to redirect the user to a separate page to initiate a new fixed asset purchase order.

1.3 Key Concepts

- Fixed Asset Purchase Orders: A specific category of procurement orders used for long-term company assets, kept distinct from standard inventory orders.
- Toolbar Filtering: A set of search and filter tools that allow users to narrow down the list of orders based on specific criteria without affecting the underlying data.
- Pagination: A display method that breaks large lists of data into manageable chunks (20 records per page) to improve performance and readability.
- Workflow State: The current status of a purchase order (e.g., pending, approved, or completed), helping users track the progress of their procurement.

1.4 Business Value

-

Improved Organization: By separating fixed asset purchase orders from general inventory, the finance and procurement teams can manage high-value company assets more effectively.

- Enhanced Visibility: The clear, tabular layout provides immediate insight into the status of orders, including how many deliveries or invoices have been processed against each asset purchase.
- Operational Efficiency: Built-in search and filter capabilities allow users to quickly locate specific documents, reducing the time spent manually searching through records.

2. Logic

2.1 Overview

This feature provides a dedicated view within the Lumi ERP system to browse and manage purchase orders specifically related to Fixed Assets. By filtering out standard operational purchases, this tool allows your team to focus exclusively on high-value asset acquisitions, ensuring better tracking and oversight of long-term company investments.

2.2 Step-by-Step Flow

1. Authentication Check: When you navigate to the Fixed Asset Purchase Order page, the system first verifies that you are logged in and authorized to view this information.
2. Data Retrieval: The system automatically requests a list of all purchase orders from the database, specifically filtering for those marked as "Fixed Assets."
3. Information Mapping: The system organizes the raw data into a clear, readable format, matching specific details like document numbers, supplier names, and financial totals to the columns in your view.
4. Display: The processed information is rendered into a table on your screen, allowing you to review the status, delivery progress, and invoicing for each asset purchase.

2.3 Key Concepts

- Fixed Asset Purchase Order: A specific type of purchase order used for acquiring long-term company assets (such as equipment or machinery) rather than day-to-day supplies.
- Workflow State: The current stage of the purchase order (e.g., pending, approved, or completed), helping you track where each order stands in the procurement process.
- Document/Reference Numbers: Unique identifiers used to cross-reference the internal system record with the supplier’s own documentation.
- Activity Counters: Summary columns that show the number of deliveries, invoices, and returns associated with a specific order, providing an at-a-glance health check of the transaction.

2.4 Business Value

- Improved Visibility: By isolating Fixed Asset orders, your team can easily monitor high-value capital expenditures without the clutter of routine operational purchases.
- Operational Efficiency: The clear summary of deliveries, invoices, and returns allows for faster reconciliation and auditing of asset acquisitions.
- Better Decision Making: Having immediate access to the status and financial totals of asset purchases ensures that stakeholders have the accurate, real-time data needed to manage the company's asset lifecycle effectively.

3. Data

3.1 Overview

This feature provides a dedicated view within the Lumi ERP system to browse and search purchase orders specifically related to Fixed Assets. By filtering out standard inventory or operational purchases, this tool allows your team to focus exclusively on high-value asset acquisitions, such as equipment, machinery, or property, ensuring better oversight of long-term company investments.

3.2 Step-by-Step Flow

1. The system receives a request to view the Fixed Asset purchase order list.
2. The system automatically filters the entire purchase order database to isolate only those records marked as "Fixed Asset."
3. The system retrieves the relevant details for these specific orders, including dates, supplier information, financial totals, and current workflow status.
4. The data is organized into a clear, readable format (including counts for deliveries, invoices, and returns) and displayed in the user interface for your review.

3.3 Key Concepts

- Fixed Asset: Long-term physical assets owned by the company that are not intended for immediate resale, such as office furniture or heavy machinery.
- Purchase Order: A formal document issued by the company to a supplier indicating the types, quantities, and agreed prices for products or services.
- Workflow State: The current stage of the purchase order in the procurement process (e.g., pending approval, received, or completed).
-

Reference Number: A unique identifier provided by the supplier, used to cross-reference the order with their own internal documentation.

3.4 Business Value

- Improved Asset Tracking: By separating Fixed Asset orders from general procurement, finance and operations teams can more easily track capital expenditures.
- Enhanced Visibility: Users can quickly see the status of an asset purchase, including how many invoices have been processed or deliveries received, without digging through unrelated operational data.
- Operational Efficiency: Centralizing this information reduces the time spent searching for specific high-value orders, allowing for faster reporting and better budget management.

BUSINESS REQUIREMENTS DOCUMENT

Company - New Purchase Order (Standard)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Purchase Order (Standard)" feature provides a structured digital form for creating purchase orders within the Lumi ERP system. This interface allows users to input supplier details, delivery information, and a list of products to be ordered. It includes built-in tools for managing itemized discounts and bulk importing product lists, ensuring that purchase orders are accurate and consistent before they are submitted for processing.

1.2 Step-by-Step Flow

1. Initialization: The user opens the form, where a unique reference code is automatically generated.
2. Header Setup: The user selects the supplier and warehouse, sets the delivery due date, and provides any necessary delivery addresses or internal notes.
3. Adding Items: The user can either manually add items to the order table or use the "Import Items" feature to upload a list via a template.
4. Discount Management: For each item, the user can open a dedicated discount modal to specify a discount by either a fixed amount or a percentage, and toggle tax inclusion.
5. Validation & Calculation: The system automatically calculates the final prices and taxes based on the inputs provided.
6. Submission: Once all details are confirmed, the user saves the form, which validates the required fields and submits the order to the system, redirecting the user to the main purchase order list.

1.3 Key Concepts

- Reference Code: A unique, system-generated identifier for the purchase order that cannot be manually edited.
- Discount Modal: A pop-up tool that allows for precise, item-level discount adjustments (either by currency amount or percentage) with real-time tax calculation.
- Import/Export Template: A feature that allows users to download a standard file format to bulk-upload product lists, reducing manual data entry.
- Dynamic Delivery Address: A field that defaults to the selected warehouse's address but allows for manual overrides if the delivery location differs.
- Workflow Status: A visual tracker that displays the lifecycle of the order (Draft, Sent, or Received) to keep stakeholders informed of the document's progress.

1.4 Business Value

- Efficiency: The ability to import items via a template significantly reduces the time spent on manual data entry for large orders.
-

Accuracy: Automated calculations for discounts and taxes minimize human error, ensuring that financial data on purchase orders is reliable.

- Standardization: By enforcing required fields and providing a structured layout, the system ensures that all purchase orders contain the necessary information for procurement and warehouse teams to operate effectively.
- Flexibility: The discount modal provides granular control over pricing, allowing the business to apply specific terms to individual products as needed.

BUSINESS REQUIREMENTS DOCUMENT

Company - New Stock Outgoing

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Stock Outgoing" feature provides a streamlined form for recording items leaving your company's inventory. This tool allows users to select a specific source location (store or warehouse), add products to be removed, and assign those items to specific expense accounts. The system automatically calculates costs and totals, ensuring that inventory records remain accurate before the document is finalized.

1.2 Step-by-Step Flow

1. Initialization: When you open the form, the system automatically loads your available stores, warehouses, and expense accounts so they are ready for selection.
2. Select Location: You must first choose the "From" location (store or warehouse). This selection is mandatory and unlocks the ability to add products.
3. Add Products: Click the "Add Product" button to create a new row. You can search for products by name, code, or SKU.
4. Automatic Data Retrieval: Once a product is selected, the system automatically displays the current stock level and the average cost for that item at your chosen location.
5. Specify Quantity: Enter the "Order Quantity." The system will instantly calculate the total cost for that line item and update the overall document totals.
6. Assign Accounts: For each product row, select the appropriate "Expense Account" to ensure the outgoing stock is tracked against the correct financial category.
7. Optional Linking: You may optionally link the outgoing stock to one or more "Service Work Orders" associated with the selected location.
8. Validation & Save: Once you click "Save," the system validates your entries (e.g., ensuring you have enough stock). If everything is correct, the document is created, and you are redirected to the details page. If there is an error, the system highlights the issue while keeping your data intact so you can make corrections.

1.3 Key Concepts

- Source Location: The specific store or warehouse from which the inventory is being removed.
- Product Search: An intelligent lookup tool that helps you find items and immediately shows you how much stock is currently available at your chosen location.
- Average Cost: A system-calculated value representing the unit cost of an item, used to determine the total financial impact of the outgoing stock.
-

Expense Account: A financial category assigned to each line item to track where the value of the outgoing stock is being charged.

- Service Work Order: An optional reference that links the outgoing stock to specific service tasks or jobs.
- Validation: A safety check performed by the system to ensure that you do not remove more stock than is currently available.

1.4 Business Value

This feature centralizes inventory management by providing a controlled, error-resistant way to record stock movement. By automating cost calculations and requiring expense account assignments, it reduces manual data entry errors and ensures that inventory records are always synchronized with financial reporting. This helps the business maintain accurate stock levels and clear visibility into where company assets are being allocated.

2. Logic

2.1 Overview

The "New Stock Outgoing" feature provides a structured way for users to record items leaving company inventory. This form acts as a digital document that tracks where stock is coming from, why it is being removed (linked to specific work orders), and the financial details associated with the items. The system ensures accuracy by automatically pulling current cost information when a product is selected, reducing manual data entry errors.

2.2 Step-by-Step Flow

1. Initiate Form: The user begins with a blank "Stock Outgoing" form.
2. Define Source: The user selects the origin of the stock (e.g., a specific warehouse or store).
3. Add Items: The user adds product rows to the form. Upon selecting a product, the system automatically retrieves the current average cost from the chosen location.
4. Input Details: The user enters the quantity to be removed and any relevant reference codes, due dates, notes, or associated service work orders.
5. Save: Once the user clicks "Save," the system bundles all the information—including the header details and the list of products—and sends it to the server to create the official stock outgoing record.

2.3 Key Concepts

- Source: The specific inventory location (such as a warehouse) from which the stock is being removed.
- Average Cost: The system-calculated value of a product, which is automatically populated to ensure financial consistency when stock leaves the inventory.
-

Service Work Order: A reference to a specific job or service task that justifies the outgoing stock, allowing for better tracking of project-related expenses.

- Expense Account: The accounting category (COA) assigned to the outgoing stock to ensure the financial impact is recorded in the correct ledger.

2.4 Business Value

- Data Accuracy: By automatically fetching the average cost and product details, the system eliminates the need for manual calculations and prevents pricing errors.
- Operational Traceability: Linking outgoing stock to specific service work orders ensures that inventory usage is clearly tied to business activities and projects.
- Streamlined Workflow: The form-based approach provides a consistent, repeatable process for staff to document inventory movements, ensuring that all necessary financial and operational data is captured before the record is finalized.

3. Data

3.1 Overview

The "New Stock Outgoing" feature provides a streamlined form for recording items leaving your company's inventory. Whether you are moving stock from a store or a warehouse, this tool allows you to select specific products, link them to relevant service work orders, and assign them to the appropriate expense accounts. The system automatically pulls current stock levels and costs to ensure your records remain accurate.

3.2 Step-by-Step Flow

1. Initialization: When you open the form, the system automatically loads a list of all available stores and warehouses (for the "From" location) and a list of expense accounts to be used for each item.
2. Select Location: You choose the source location (Store or Warehouse) from which the stock is being removed.
3. Add Products: You search for products by typing their SKU, name, or code. As you select a product, the system automatically retrieves and displays the current stock quantity and average cost for that specific location.
4. Link Work Orders (Optional): You can search for and attach one or more service work orders to the transaction. The system filters these results to ensure you only see work orders associated with your selected location.
5. Assign Details: For each product row, you select the appropriate expense account and enter the quantity being removed.
6. Submission: Once you provide a reference number, due date, and any necessary notes, you submit the form to finalize the stock outgoing record.

3.3 Key Concepts

- Source Location: The specific store or warehouse where the inventory is currently held and from which it is being removed.
- Product Search: An intelligent lookup tool that helps you find items quickly by SKU, name, or product code, while simultaneously showing you how much is currently in stock.
- Service Work Order: A specific job or task record that can be linked to the outgoing stock to track why the inventory was used.
- Expense Account: A financial category used to track the cost of the outgoing items for accounting purposes.
- Stock Outgoing Record: The final document that captures the "who, what, where, and why" of the inventory movement.

3.4 Business Value

- Accuracy: By automatically pulling real-time stock levels and average costs, the system reduces manual data entry errors and ensures financial reporting is precise.
- Efficiency: The search-as-you-type functionality and pre-loaded location lists allow staff to process inventory movements quickly.
- Traceability: Linking outgoing stock to specific service work orders and expense accounts provides a clear audit trail, making it easier to understand inventory consumption and manage costs across different departments or projects.

BUSINESS REQUIREMENTS DOCUMENT

Company - Stock Outgoing Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Stock Outgoing Details" feature provides a centralized view for managing the lifecycle of a stock outgoing document. It allows authorized users to track, review, and process the movement of inventory from a specific location. The interface is designed to be state-aware, meaning the options available to the user change automatically based on whether the document is a draft, confirmed, approved, or cancelled.

1.2 Step-by-Step Flow

1. Viewing the Document: When you open a stock outgoing document, the system displays the full header information (such as reference codes, dates, and source locations) and a table of all products involved.
2. Workflow Management: Depending on the current status of the document, you will see different action buttons:

* Draft: You can print, confirm the document, or cancel it. You can also edit the details.

* Confirmed: You can print, approve, or cancel the document. Editing is disabled to ensure data integrity.

* Approved: The document is finalized. You can only print it. Additional accounting information (such as the reversal account and journal reference) becomes visible.

* Cancelled: You can print the document or reset it back to a draft state if further changes are needed.

3. Approval Process: If you choose to approve a confirmed document, you are taken to a dedicated approval screen. Here, you can review the final costs (which are recalculated to ensure accuracy) and assign a "reversal account" for each item. Once saved, the document is officially approved and the accounting journal is generated.

1.3 Key Concepts

- Workflow State: The status of the document (Draft, Confirmed, Approved, or Cancelled) which dictates what actions you can take and what information is visible.
- Reversal Account: An accounting category assigned during the approval process that determines how the stock movement is recorded in the financial system.
- Stock Check: A validation process that occurs when you move a document from "Draft" to "Confirmed" to ensure the requested quantity is actually available in the warehouse.
- Recalculated Cost: The system automatically updates the average cost of items at the moment of approval to ensure the financial records reflect the most current inventory valuation.

1.4 Business Value

This feature ensures accurate inventory control and financial reporting by enforcing a strict approval workflow. By separating the "Draft" and "Approval" stages, the system prevents unauthorized changes to confirmed documents and ensures that accounting data—specifically the cost of goods and reversal accounts—is accurate and up-to-date at the exact moment the stock leaves the facility. This reduces manual errors and provides a clear audit trail for all inventory movements.

2. Logic

2.1 Overview

The "Stock Outgoing Details" feature provides a comprehensive view of a single inventory outgoing document. It allows users to see all relevant information—such as the source location, product details, and current status—in one place. The system also includes a workflow management tool that allows users to transition the document through various stages (such as confirming, canceling, or resetting) directly from the view page.

2.2 Step-by-Step Flow

1. Loading the Document: When you open a stock outgoing record, the system automatically retrieves all header information (like dates, creator, and reference codes) and the full list of items in a single request.
2. Displaying Information: The page populates two main areas:

* Header Details: Displays administrative information, including the source (Warehouse or Store), approval dates, and the current workflow status.

* Item Table: Lists every product included in the outgoing stock, showing quantities, costs, and account details.

3. Conditional Visibility: Certain fields, such as the "Journal" reference or "Reversal Account," are hidden until the document reaches the "Approved" status to ensure users only see relevant data for the current stage.
4. Workflow Actions: Depending on the document's current status, the system displays action buttons (e.g., Confirm, Cancel, or Reset). Clicking these buttons immediately updates the document's status.
5. Automatic Refresh: Once an action is performed, the page automatically updates the workflow bar, dates, and visibility of specific fields based on the new status, ensuring the information remains accurate without needing to manually refresh the page.

2.3 Key Concepts

– Workflow State: The current stage of the document (e.g., Draft, Confirmed, Approved, or Cancelled), which determines which actions you can take and what information is visible.

– Header Mapping: The process of organizing administrative data (like dates and reference codes) into a clear, readable summary at the top of the page.

- Item Table: A detailed list of all products associated with the outgoing stock, including financial data like average costs and account codes.
- Workflow Actions: Direct commands (Confirm, Cancel, Reset) that change the document's status and trigger immediate updates to the page display.

2.4 Business Value

This feature centralizes inventory management by providing a "single source of truth" for outgoing stock. By displaying all necessary details and workflow controls on one screen, it reduces the need for users to navigate between multiple pages. The automatic status updates and conditional visibility ensure that users always have the most accurate, stage-appropriate information, which minimizes errors and streamlines the inventory approval process.

3. Data

3.1 Overview

The "Stock Outgoing Details" feature provides a comprehensive view of a single inventory outgoing transaction. It allows users to see all relevant information—such as the source warehouse, items being moved, and the current status of the transaction—in one centralized location. The feature also manages the lifecycle of the transaction, guiding it from a draft state through to final approval and accounting integration.

3.2 Step-by-Step Flow

1. View Details: When you open a stock outgoing record, the system retrieves the full document, including the header information (such as dates, references, and status) and the list of all items involved.
2. Workflow Management: Depending on the current status of the document, you can perform specific actions:

* Draft: You can confirm the document (which checks if the items are available in stock), cancel it, or edit the details.

* Confirmed: You can proceed to the approval screen or cancel the document.

* Approved: The document is finalized; no further workflow changes are allowed, but you can print the record.

* Cancelled: You can reset the document back to a draft state if needed.

3. Approval Process: When you select "Approve," you are taken to a dedicated screen to finalize the transaction. Saving this screen updates the costs, assigns reversal accounts, generates the necessary accounting journal entry, and marks the document as officially approved.

3.3 Key Concepts

–

Workflow State: The current stage of the document (e.g., Draft, Confirmed, Approved, or Cancelled), which determines which actions you are permitted to take.

- Stock Availability Check: A validation step that occurs during confirmation to ensure that the requested items are actually available in the warehouse before moving forward.
- Journal Entry: An automated accounting record created upon final approval that reflects the financial impact of the stock movement.
- Reversal Account: A specific accounting account used to balance the transaction, which becomes visible only after the document has been officially approved.

3.4 Business Value

- Operational Transparency: Provides a single source of truth for stock movements, ensuring that warehouse staff and managers can see exactly what is being moved and why.
- Error Prevention: By validating stock availability before confirmation, the system prevents the creation of invalid or impossible outgoing transactions.
- Accounting Accuracy: Automating the generation of journal entries and the assignment of reversal accounts upon approval reduces manual data entry errors and ensures that inventory costs are accurately reflected in the company's financial records.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders Standard (External) - New Purchase

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Franchise Purchase Order Standard (External)" feature allows users to create new purchase orders for external suppliers within the Lumi ERP system. This interface provides a structured way to select a destination store, choose a supplier, define the products and quantities required, and set delivery expectations. The system ensures data accuracy through built-in validation before the order is officially submitted to the inventory management workflow.

1.2 Step-by-Step Flow

1. Initialization: Upon opening the page, the system verifies your access permissions and automatically loads the necessary lists for stores, suppliers, and products.
2. Header Information: You select the destination store ("Deliver To") and the supplier ("From Supplier"). You may also optionally enter a supplier reference code, a due date, and any additional notes.
3. Adding Items: You add products to the order by selecting them from the list and specifying the desired order quantity. You can add multiple unique products to a single order.
4. Validation: When you click "Save," the system checks for errors, such as missing required fields, quantities of zero, or duplicate products.
5. Submission: If the form is valid, the order is sent to the system. The server then calculates totals, prices, and stock levels, and assigns a unique document number to the order.
6. Completion: If the submission is successful, the order is created. If there are issues, the system will highlight the specific errors for you to correct.

1.3 Key Concepts

- Deliver To: The specific store location that will receive the items ordered.
- From Supplier: The external vendor or supplier providing the goods.
- Supplier Reference Code: An optional tracking number provided by the supplier for their own internal records.
- Due At: The target date by which the order is expected to be delivered.
- Validation: Automated checks that prevent incomplete or incorrect orders (e.g., ensuring you don't order the same product twice on one form).
- Product Entries: The list of items included in the purchase order, where you define what to buy and how much.

1.4 Business Value

This feature streamlines the procurement process for franchises by providing a standardized, error-proof method for ordering inventory from external suppliers. By automating the validation of order details and integrating directly with the inventory workflow, it reduces manual data entry errors, ensures that all necessary information is captured before an order is placed, and provides clear visibility into supply chain costs and stock requirements.

2. Logic

2.1 Overview

This feature enables the creation of a new "External" purchase order within the Lumi ERP system. It allows users to request products from an external supplier to be delivered to a specific franchise store. The system ensures data accuracy by validating all entries before saving the order and automatically calculating financial details like supply prices and average costs.

2.2 Step-by-Step Flow

1. Data Entry: The user fills out the purchase order form, including the destination store, the supplier, the due date, any relevant notes, and a list of products with their requested quantities.
2. Validation: When the user clicks "Save," the system immediately checks for errors:

– Ensures the destination store and supplier are selected.

– Confirms at least one product is included.

– Verifies that all order quantities are greater than zero.

– Checks that no product is listed more than once.

3. Processing: If the data is valid, the system creates the purchase order record. It automatically assigns a status of "Draft" and categorizes it as an "External" order.
4. Item Calculation: For every product in the order, the system automatically retrieves the current supply price and the company's average cost to ensure financial accuracy.
5. Confirmation: Once saved, the system returns the finalized order details, including a unique reference code generated by the system.

2.3 Key Concepts

– External Purchase Order: A formal request for goods sent to a supplier outside of the immediate company network.

– Validation: A safety check performed by the system to prevent incomplete or incorrect orders from being processed.

–

Draft State: The initial status of a new order, indicating it has been created but is not yet finalized or sent to the supplier.

- Reference Code: A unique identifier automatically generated by the system for every new purchase order to help with tracking and record-keeping.
- Supply Price & Average Cost: Financial data points automatically pulled by the system to provide accurate valuation for the items being ordered.

2.4 Business Value

This feature streamlines the procurement process for franchise stores by providing a standardized, error-proof way to order inventory. By automating the calculation of costs and enforcing strict validation rules, the system reduces manual data entry errors, ensures financial consistency across the organization, and provides a clear audit trail for all external purchases.

3. Data

3.1 Overview

The "Franchise Purchase Order" feature allows users to create new external purchase orders within the Lumi ERP system. This process ensures that orders are accurately recorded, validated, and linked to the correct store and supplier. By automating the calculation of costs and inventory levels at the time of creation, the system maintains data integrity and provides immediate visibility into the financial impact of each order.

3.2 Step-by-Step Flow

1. Validation: The system checks that the order includes a destination store, a supplier, and at least one product. It also ensures that the order quantity for each product is greater than zero and that no product is listed more than once.
2. Order Header Creation: The system creates the main order record, assigning it a unique reference code, setting its status to "Draft," and recording details like the due date and any provided notes.
3. Item Processing: For every product in the order, the system automatically retrieves the current supplier price, the store's existing inventory level, and the company’s average cost for that item.
4. Financial Calculation: The system calculates the total order amount for each item (quantity multiplied by the current supply price) and saves these details alongside the order.
5. Finalization: The entire order, including the header and all calculated item details, is saved to the system as a single, complete transaction.

3.3 Key Concepts

- External Purchase Order: A formal request sent to an outside supplier to procure goods for a specific franchise store.
- Draft State: The initial status of a new order, allowing for review before it is processed further.
- Atomic Transaction: A safety mechanism that ensures all parts of an order (the header and all individual items) are saved together; if any part fails, the entire order is not created, preventing incomplete data.
- Server-Side Calculation: The process where the system automatically determines prices and totals based on current data, ensuring accuracy and reducing manual entry errors.

3.4 Business Value

- Data Accuracy: By automatically fetching current supply prices and inventory levels, the system eliminates manual calculation errors and ensures the order reflects the most up-to-date financial information.
- Operational Efficiency: Standardizing the creation process ensures that all necessary information is captured upfront, reducing the need for follow-up corrections.
- Reliability: The use of strict validation rules and atomic transactions ensures that every purchase order created is complete, valid, and ready for the next stage of the supply chain workflow.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal NEW

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Franchise Purchase Order - Internal" feature allows staff to create new internal purchase orders within the inventory module. This tool streamlines the process of requesting stock from a warehouse for a specific store, ensuring that all necessary supply details are captured accurately before the order is processed.

1.2 Step-by-Step Flow

1. Navigation: Access the form via the Inventory module in the main navigation panel.
2. Header Entry: Fill in the order details, including the source warehouse, destination store, supplier information, reference code, due date, and any additional notes.
3. Product Selection: Add items to the order using the product table, specifying the store quantity, order quantity, supply price, and any specific remarks for each item.
4. Validation: The system checks that all required fields are completed and that at least one product has been added to the order.
5. Submission: Click the "Save" button to finalize the order. The system will save the record as a "Draft" and automatically redirect you to the newly created order's detail page.
6. Cancellation: If you decide not to proceed, you can click the "Cancel" button to discard the current entry and return to the previous screen.

1.3 Key Concepts

- Workflow Status: A tracker that displays the current stage of the order (e.g., Draft, Confirmed, Sent, Approved), helping users monitor the order's progress.
- Internal Order: A specific type of purchase order used for moving or requesting stock between internal company locations, such as from a central warehouse to a franchise store.
- Line Items: The individual products included in a single purchase order, each with its own quantity and pricing details.
- Draft State: The initial status of a new order, allowing users to save and review information before it is officially confirmed or sent.

1.4 Business Value

- Operational Efficiency: Centralizes the internal ordering process, reducing manual paperwork and communication errors between warehouses and stores.
-

Data Accuracy: Enforces mandatory field requirements, ensuring that every purchase order contains the necessary information for fulfillment.

- Improved Visibility: Provides a clear, status-driven workflow that allows management to track orders from creation through to approval.

2. Logic

2.1 Overview

The "Franchise Purchase Orders - Internal" feature allows users to create new internal purchase orders within the Lumi ERP system. This process captures essential order details—such as the source warehouse, destination store, supplier information, and specific product quantities—and saves them as a "draft" order. This ensures that all necessary procurement data is recorded accurately before the order moves forward in the supply chain workflow.

2.2 Step-by-Step Flow

1. Data Validation: The system checks that all required order information and product line items are provided. If any information is missing, the process stops and alerts the user.
2. Order Initialization: The system creates a new purchase order record, automatically setting the status to "draft."
3. Header Recording: The system saves the primary order details, including the warehouse, store, supplier, reference codes, due dates, and any additional notes.
4. Line Item Processing: The system iterates through the list of products provided, linking each item (including quantities, pricing, and remarks) to the newly created purchase order.
5. Confirmation: Once all data is successfully saved, the system returns a unique order ID, allowing the user to be automatically redirected to the details page of the newly created order.

2.3 Key Concepts

- Draft Status: The initial state of a new purchase order, indicating that the document has been created but is not yet finalized or active.
- Header Record: The main container for the purchase order that holds high-level information like the supplier, destination store, and due date.
- Line Items: The individual products associated with a purchase order, including specific details like the quantity requested and any store-specific remarks.
- Validation: A safety check performed by the system to ensure that no incomplete or invalid data is saved to the database.

2.4 Business Value

- Operational Efficiency: By automating the creation of internal purchase orders, staff can quickly generate procurement requests without manual data entry errors.
- Data Integrity: The structured validation process ensures that every order contains all necessary information, preventing downstream issues in inventory management.
- Seamless Workflow: Automatically transitioning the user to the order details page after creation provides a smooth, intuitive experience, allowing for immediate review or further action on the order.

3. Data

3.1 Overview

The "Internal Franchise Purchase Order" feature allows your team to create and manage new purchase orders specifically for internal inventory needs. This system streamlines the process of requesting items from a warehouse for a specific store, ensuring that all necessary details—such as quantities, pricing, and delivery timelines—are captured accurately in one place.

3.2 Step-by-Step Flow

1. Data Validation: The system checks the information provided in the request to ensure all required fields (such as store location, supplier details, and delivery dates) are present and correctly formatted.
2. Transaction Initiation: The system opens a secure process to ensure that the order and its associated items are saved together as a single, complete unit.
3. Order Creation: A primary purchase order record is created, capturing high-level details like the warehouse destination, the store requesting the items, and the expected due date.
4. Item Processing: The system adds the specific list of products to the order, recording the requested quantities, pricing, and any specific notes for each item.
5. Confirmation: Once all data is saved, the system returns a complete summary of the newly created purchase order and its line items for your review.

3.3 Key Concepts

- Purchase Order: A formal document that tracks the request for goods from a warehouse to a specific store.
- Line Items: The individual products included within a single purchase order, each with its own specific quantity and pricing details.

- Workflow State: The current status of the order (e.g., pending, approved, or in progress) as it moves through the supply chain.
- Transaction: A safety mechanism that ensures that if any part of the order fails to save, the entire order is rolled back to prevent incomplete or "broken" data.

3.4 Business Value

- Operational Efficiency: By centralizing the creation of internal orders, staff can quickly request inventory without manual paperwork or fragmented communication.
- Data Accuracy: Automated validation ensures that every order contains the necessary information, reducing errors in shipping and billing.
- Improved Inventory Visibility: Because every order and its specific items are tracked in the system, management gains a clearer view of stock movement between warehouses and stores.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Standard Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Standard Details feature provides a centralized view for managing purchase orders between a franchise and its suppliers. It allows users to track the lifecycle of an order—from initial draft to final receipt—while providing clear visibility into order items, financial totals, and current workflow status.

1.2 Step-by-Step Flow

1. Initialization: When you open a specific purchase order, the system automatically retrieves the order header information and the list of items included in that order.
2. Review: You can view the order details, including supplier information, delivery destination, and financial summaries (subtotals, discounts, and taxes).
3. Workflow Management: Depending on the current status of the order, you can perform specific actions:

* Draft: You can confirm the order to move it to "Store Confirmed" or cancel it.

* Store Confirmed: You can send the order to the supplier to move it to "Ordered" or cancel it.

* Ordered: You can initiate the "Receive" process to verify items and finalize the order as "Store Received."

* Cancelled: You can reset the order back to "Draft" if needed.

4. Confirmation: For critical actions (like confirming, cancelling, or resetting), a pop-up window will appear to ensure you intend to proceed before the system updates the status.
5. Finalization: Once the "Receive" action is completed, the system updates the order status to "Store Received" and automatically updates the store's stock records.

1.3 Key Concepts

- Workflow Status: The current stage of the order (Draft, Store Confirmed, Ordered, or Store Received), which determines which buttons and actions are available to you.
- Order Items Table: A detailed list of products in the order, showing quantities, pricing, discounts, and the final amount for each line item.
- Action Buttons: Context-sensitive controls that allow you to progress the order through its lifecycle or perform administrative tasks like printing or exporting data.
- Review State: A specific view used during the receiving process that allows you to verify order details and update notes or reference numbers before finalizing the receipt of goods.

1.4 Business Value

This feature streamlines inventory management by providing a single source of truth for franchise procurement. By digitizing the workflow, it reduces manual errors in order tracking, ensures that stock levels are accurately updated upon receipt, and provides clear accountability through recorded timestamps and user tracking. This ultimately helps franchise owners maintain better control over their supply chain and financial reporting.

2. Logic

2.1 Overview

The Franchise Purchase Order feature provides a centralized view for managing inventory procurement. It allows users to view the full details of a purchase order, including header information (such as supplier details, dates, and financial totals) and a breakdown of the specific items being ordered. The system automatically adjusts the page display based on the current status of the order to ensure users only interact with relevant information.

2.2 Step-by-Step Flow

1. Data Retrieval: When a user opens a specific purchase order, the system simultaneously fetches the order header (general information) and the list of line items (the products being ordered).
2. Header Mapping: The system maps the retrieved order data to the corresponding fields on the screen, such as Document Number, Supplier Name, Due Date, and financial summaries like Subtotal and Tax.
3. Item Mapping: The system populates the product table by mapping item details—such as SKU, Product Name, Order Quantity, and pricing—into the appropriate columns.
4. Status Validation: The system checks the "workflow state" of the order.
5. UI Rendering:

* If the order is marked as "placed," the page displays the full details and item list, ready for processing.

* If the order is in any other state, the system hides the item list and displays a "Not awaiting receipt" message to prevent unnecessary actions.

2.3 Key Concepts

- Workflow State: A status indicator that determines whether an order is ready for receipt or if it is in a different stage of the procurement process.
- Header Details: The high-level summary of the purchase order, including administrative data (who created it), dates, and total financial values.
- Line Items: The individual products included in the purchase order, displayed in a table format with specific quantities and pricing per item.
-

Empty State: A user-friendly interface view that appears when an order does not meet the criteria for further action, preventing user confusion.

2.4 Business Value

This feature streamlines inventory management by providing a clear, consistent view of franchise purchase orders. By automatically filtering the display based on the order's status, the system reduces manual errors and ensures that staff only focus on orders that are ready for receipt. This improves operational efficiency and provides better visibility into procurement costs and supplier commitments.

3. Data

3.1 Overview

The Franchise Purchase Order feature provides a comprehensive view of procurement documents within the Lumi ERP system. It allows users to view both the high-level summary of a purchase order (such as dates, supplier information, and financial totals) and the specific list of items included in that order. This ensures that franchise managers and staff have clear visibility into their ordering process, from creation through to final receipt.

3.2 Step-by-Step Flow

1. Load Order Summary: When a user selects a specific purchase order, the system retrieves the header information, including document references, supplier details, store location, and financial totals (subtotals, taxes, and final amounts).
2. Display Header Details: The system maps this information to the "Details" view, providing a clear summary of the order's status, timeline, and financial breakdown.
3. Load Line Items: The system retrieves the list of products associated with the order. This list is organized by line number to ensure the order of items is preserved.
4. Display Item Table: The system populates a table with the item details, including product names, codes, quantities ordered versus received, pricing, and any applicable discounts.

3.3 Key Concepts

- Purchase Order Header: The top-level information for an order, containing administrative data like dates, supplier names, and overall financial totals.
- Line Items: The individual products or services included within a single purchase order, detailing specific quantities and costs per item.
- Financial Breakdown: A clear view of the order's costs, including subtotals, discounts, tax calculations, and the final total amount.

- Order Tracking: The ability to see key milestones such as when an order was created, placed, and received, as well as the due date.

3.4 Business Value

- Operational Transparency: Provides staff with an immediate, accurate view of what was ordered, where it is being delivered, and the current status of the shipment.
- Financial Accuracy: By clearly separating subtotals, discounts, and taxes, the system reduces errors in procurement accounting and helps users verify that invoices match the original order.
- Improved Efficiency: Centralizing all order details and itemized lists in one view saves time for franchise staff, allowing them to quickly resolve discrepancies between ordered and received goods.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Returns - New

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Franchise Purchase Returns" feature allows store staff to initiate a return of goods back to the franchisor. This process ensures that inventory adjustments are tracked accurately, linked to original purchase orders, and follow a standardized workflow from the initial draft stage through to final approval.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves a list of available stores and internal suppliers (franchisors).
2. Selection: The user selects the store initiating the return and the specific internal supplier receiving the goods.
3. Order Linking: Once the store and supplier are selected, the user can search for and select the relevant original purchase order.
4. Product Review: The system populates a table showing the products from the selected order, including details like current store quantity, original order quantity, and the maximum amount allowed for return.
5. Data Entry: The user enters the specific quantity to be returned for each item and provides a reason for the return.
6. Submission: Upon clicking "Save," the system records the return as a "Draft" and redirects the user to a confirmation page to view the status of the request.

1.3 Key Concepts

- Workflow Status: A visual tracker that displays the current stage of the return (Draft, Confirmed, Sent, or Approved), ensuring transparency throughout the process.
- Internal Supplier: A restricted list of suppliers representing the franchisor, ensuring returns are only processed within the authorized franchise network.
- Reference Code: A system-generated, unique identifier for the return document, ensuring every transaction is easily traceable.
- Max Return Quantity: A safety control that prevents users from returning more items than were originally purchased.

1.4 Business Value

- Accuracy: By linking returns to original purchase orders, the system prevents errors and ensures that inventory levels are adjusted based on verified historical data.
-

Efficiency: Automating the retrieval of store and supplier lists reduces manual data entry and minimizes the risk of selecting incorrect entities.

- Compliance: The structured workflow ensures that all returns are documented and approved according to company policy, providing a clear audit trail for franchise operations.

2. Logic

2.1 Overview

The Franchise Purchase Returns feature allows store users to initiate a return of goods back to the franchisor. This process is designed specifically for "internal" returns, ensuring that items are correctly tracked from the store back to the central supplier. The system guides the user through selecting the store, the supplier, and the specific purchase order associated with the items being returned.

2.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically populates the "Return From" (Store) and "Return To" (Supplier) dropdowns. The supplier list is restricted to internal franchisor entities only.
2. Selection: The user selects the store and the internal supplier.
3. Order Search: Once a store and supplier are selected, the user can search for a specific purchase order. The search activates after the user types at least three characters.
4. Product Loading: Once a purchase order is selected, the system displays the relevant products associated with that order.
5. Submission: The user completes the return details (such as quantities and notes) and submits the form.
6. Confirmation: Upon successful submission, the return is saved as a "draft" and the user is redirected to a confirmation page.

2.3 Key Concepts

- Internal Return: A specific type of return process where goods are sent back to the franchisor rather than an external vendor.
- Draft Workflow State: The initial status of a return record, indicating it has been created but is still in the early stages of processing.
- Searchable Purchase Order: A dynamic field that filters available orders based on the store and supplier selected, ensuring only relevant data is displayed.
- Sender/Receiver Mapping: The system automatically assigns the store as the "sender" and the franchisor as the "receiver" to ensure accurate inventory accounting.

2.4 Business Value

- Accuracy: By restricting the supplier list to internal entities and linking returns to specific purchase orders, the system prevents errors in inventory reconciliation.
- Efficiency: The search-as-you-type functionality for purchase orders saves time for store staff by quickly narrowing down the correct transaction.
- Standardization: Automating the "internal" return type and workflow state ensures that all franchise returns follow a consistent process, making it easier for the finance and warehouse teams to track returned stock.

3. Data

3.1 Overview

The Franchise Purchase Return feature allows users to formally initiate the return of inventory items from a specific franchise store back to an internal supplier. This process ensures that all returns are tracked accurately within the Lumi ERP system, linking the returned goods to their original purchase orders and maintaining a clear audit trail of inventory movement.

3.2 Step-by-Step Flow

1. Select Origin: The user selects the specific franchise store that is initiating the return from a list of available locations.
2. Select Destination: The user selects the internal supplier receiving the returned goods from a filtered list of internal entities.
3. Enter Return Details: The user provides necessary information, including a reference code, the type of return, the current status of the workflow, and any relevant notes.
4. Identify Items: The user specifies the product and quantity being returned, linking these items to the original purchase order.
5. Finalize Submission: The system saves the return request, ensuring that both the high-level return information (the header) and the specific item details are recorded together as a single, complete transaction.

3.3 Key Concepts

- Franchise Purchase Return: A formal record used to track inventory being sent back from a store to an internal supplier.
- Internal Supplier: A business entity within the organization that acts as a source of supply for franchise stores.

- Workflow State: The current stage of the return process (e.g., pending, approved, or completed), which helps manage the lifecycle of the return.
- Reference Code: A unique identifier assigned to the return request to make it easy to search for and track in the system.
- Transaction: A safety mechanism that ensures the return header and the individual items are saved simultaneously; if one part fails, the entire record is not saved, preventing data errors.

3.4 Business Value

- Inventory Accuracy: By formalizing the return process, the system ensures that stock levels at both the franchise store and the internal supplier remain accurate and up-to-date.
- Operational Efficiency: Automating the return workflow reduces manual paperwork and minimizes errors associated with tracking returned goods.
- Improved Accountability: Linking returns to specific purchase orders provides clear visibility into why items are being returned and ensures that the correct internal entities are credited or debited accordingly.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Return - Standard NEW

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Franchise Purchase Return" feature allows users to initiate a return of products from a franchise store back to a supplier. This process is designed to be simple and controlled, ensuring that returns are accurately documented and do not exceed the quantities originally ordered or currently held in stock.

1.2 Step-by-Step Flow

1. Initialization: When opening the page, the system automatically loads available store locations and internal suppliers to populate the selection menus. A unique document number is also generated for the return.
2. Header Information: The user selects the "Return From" location (the store) and the "Return To Supplier" location. Optionally, the user can link the return to a specific previous purchase order, add a reference number, and include any relevant notes.
3. Item Selection: Once the return context is set, the system displays the relevant products. Key details—such as current store quantity, original order quantity, and the maximum allowed return quantity—are automatically populated and locked to prevent manual errors.
4. Return Details: For each item, the user enters the specific quantity they wish to return and provides a reason for the return. The system validates that the return quantity does not exceed the maximum allowed limit.
5. Submission: Upon clicking "Save," the system processes the data and creates the return record. The user is then automatically redirected to the details page for that specific return, where it is marked as a "Draft."
6. Cancellation: If the user decides not to proceed, they can click "Cancel" to discard all changes and return to the main list page.

1.3 Key Concepts

- Document Number: A unique, system-generated identifier for the return, formatted to include the warehouse location and date for easy tracking.
- Maximum Return Quantity: A safety limit calculated by the system to ensure that users cannot return more items than were originally ordered or are currently available in the store.
- Draft Status: The initial state of a new return, indicating that the record has been created but is still in the early stages of the approval workflow.
- Validation: Automated checks that ensure required fields are filled and that return quantities remain within permissible limits before the data is saved.

1.4 Business Value

This feature streamlines the inventory management process by providing a standardized way to handle returns. By automating the population of product data and enforcing strict quantity limits, it reduces the risk of manual entry errors and ensures that all returns are properly linked to existing purchase records. This creates a clear audit trail and helps maintain accurate inventory levels across the franchise network.

2. Logic

2.1 Overview

The "Franchise Purchase Return" feature allows users to initiate a formal return of items previously purchased by a franchise. This process ensures that inventory adjustments are tracked accurately by linking the return to specific stores, suppliers, and original purchase orders. The system provides a structured form to capture return details, validate quantities, and document the reason for the return, ultimately creating a draft record for further processing.

2.2 Step-by-Step Flow

1. Access & Initialization: When a user opens the page, the system verifies their identity. If authorized, it prepares a new, unique form and populates dropdown menus with available store locations and internal suppliers.
2. Form Completion: The user fills out the return header (e.g., which store is returning the items, which supplier is receiving them, and optional reference numbers or notes).
3. Order Linking: If applicable, the user can search for and select a specific original purchase order. The system helps narrow down results based on the selected store and supplier once the user types at least three characters.
4. Item Entry: The user adds items to the return, specifying the quantity to be returned and the reason for the return. The system ensures these entries stay within allowed limits (such as the maximum returnable quantity).
5. Submission: Upon clicking "Save," the system bundles all information—including header details and the list of items—and sends it to the database.
6. Confirmation: Once successfully saved, the user is automatically redirected to a details page where the return is displayed in a "Draft" status, allowing for final review or further action.

2.3 Key Concepts

- Franchise Purchase Return: A formal document used to track inventory being sent back from a franchise location to a supplier.
-

Draft Status: The initial state of a new return, indicating that the record has been created in the system but is still open for review or modification before final processing.

- Source Order: An optional link to the original purchase transaction, which helps the system validate return quantities and maintain a clear audit trail.
- On-Demand Search: A feature that fetches specific purchase order data only when needed (after typing three characters), keeping the interface fast and responsive.

2.4 Business Value

- Inventory Accuracy: By requiring specific return reasons and linking to original orders, the business maintains precise control over stock levels and reduces discrepancies.
- Operational Efficiency: The automated lookup of stores and suppliers, combined with the ability to search for purchase orders, minimizes manual data entry and reduces the risk of human error.
- Audit Readiness: Every return is assigned a unique document number and saved as a draft, ensuring that all returns are documented and traceable from the moment they are initiated.

3. Data

3.1 Overview

The "Franchise Purchase Return" feature provides a standardized way for users to record the return of items from a franchise store back to a supplier. This digital form ensures that all necessary details—such as the origin of the return, the destination supplier, the original purchase order, and specific item quantities—are captured accurately and saved into the system.

3.2 Step-by-Step Flow

1. Page Initialization: When a user opens the page, the system verifies their access permissions. It then automatically loads the available list of stores and internal suppliers to populate the "Return From" and "Return To Supplier" dropdown menus.
2. Form Entry: The user selects the store initiating the return and the supplier receiving the goods.
3. Order Search: If the return is linked to a specific purchase, the user can search for the original Franchise Purchase Order. The system will suggest relevant orders once the user types at least three characters, filtering results based on the selected store and supplier.
4. Item Details: The user enters the specific products being returned, including the quantities (current store stock vs. the amount being returned) and the reason for the return.
5.

Submission: Once the user completes the form and clicks "Save," the system bundles all the information—including header details and the list of items—and submits it to the database to finalize the return record.

3.3 Key Concepts

- Return From: The specific store location that is sending the items back.
- Return To Supplier: The internal supplier designated to receive the returned items.
- Franchise Purchase Order: An optional reference to the original order, which helps the system track the history of the items being returned.
- On-Demand Search: A feature that only retrieves purchase order data after the user provides enough input (3+ characters), ensuring the system remains fast and responsive.
- Return Items: The individual line items within the return, which track specific product quantities and the reason for each return.

3.4 Business Value

This feature streamlines inventory management by replacing manual or informal return processes with a structured digital workflow. By linking returns to specific stores, suppliers, and original purchase orders, the business gains better visibility into inventory movement, improves the accuracy of stock records, and creates a clear audit trail for all franchise-related returns.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Store Work Order

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Work Orders" feature provides a dedicated view within the Inventory module to track and manage stock orders specifically linked to service work orders. This interface allows users to see a comprehensive list of these orders, filter them by specific criteria, and easily navigate to the details of individual stock or service records.

1.2 Step-by-Step Flow

1. Initial Load: When you navigate to the "Work Orders" tab, the system automatically retrieves all stock orders associated with service work orders.
2. Search and Filter: You can narrow down the list using the search toolbar. You may filter by specific stock order codes, service work order codes, date ranges, store or warehouse locations, and current status.
3. Refining Results: Once you enter your desired criteria and click "Search," the system updates the table to display only the records that match your filters.
4. Data Display: The table presents key information for each order, including dates, locations, status, and financial amounts.
5. Navigation: You can click on a specific row to open the detailed view for that stock order or its associated service work order.

1.3 Key Concepts

- Work Orders Tab: A specialized view within the Inventory module that filters all stock activity to show only those related to service work.
- Search Toolbar: A set of input fields that allows you to query the database for specific orders without needing to browse the entire list.
- Status: The current lifecycle stage of an order (e.g., draft, confirmed, sent, or received), which helps you track progress.
- Nullable Fields: Certain information, such as store or warehouse names, may appear blank if the original record is no longer available; the system handles this gracefully to ensure the table remains readable.
- Mapping Rules: The logic that ensures data from the system is correctly organized into the table columns (e.g., ensuring the "Date" column always shows the correct creation date).

1.4 Business Value

This feature streamlines inventory management by centralizing service-related stock orders in one place. By providing robust filtering and clear visibility into order status and amounts, it reduces the time spent searching for

information and helps staff quickly identify which service work orders are pending, in progress, or completed. This improves operational efficiency and ensures that inventory levels are accurately aligned with service requirements.

2. Logic

2.1 Overview

The "Store Work Order" feature provides a dedicated view within the inventory system to track stock orders specifically linked to service work orders. This interface allows users to search, filter, and monitor the status of these orders, ensuring that inventory movements related to service tasks are transparent and easily accessible.

2.2 Step-by-Step Flow

1. Initial Load: When you open the Work Orders tab, the system automatically retrieves a list of stock orders filtered specifically for service work orders.
2. Applying Filters: You can use the search toolbar to narrow down results. You may filter by specific stock order codes, service work order codes, date ranges, store locations, warehouse locations, or current workflow status.
3. Data Retrieval: Once you click "Search," the system sends your criteria to the database. Only the filters you have actively filled in are applied to the search.
4. Displaying Results: The system receives the data and populates the table. Each row represents a stock order, displaying key details such as the order amount, receipt status, the store and warehouse involved, and the user who last updated the record.
5. Navigation: You can click on the Stock Order reference or the Service Work Order reference within any row to jump directly to the details of that specific record.

2.3 Key Concepts

- Stock Order: A request for inventory items that need to be moved or allocated.
- Service Work Order: The specific maintenance or service task that triggered the need for these inventory items.
- Workflow State: The current progress of the order (e.g., pending, in-progress, or completed).
- Filtering: The ability to narrow down a large list of orders based on specific criteria like dates, locations, or status to find exactly what you need.
- Data Mapping: The process where the system takes raw information from the database and organizes it into the clear, readable columns you see in your table.

2.4 Business Value

This feature streamlines inventory management by bridging the gap between service tasks and stock requirements. By providing a centralized, searchable view of work-related stock orders, staff can:

* Improve Accountability: Easily see who last updated an order and its current status.

* Enhance Efficiency: Quickly locate specific orders without manually searching through general inventory logs.

* Better Coordination: Ensure that the right parts are arriving at the right store or warehouse at the right time to support ongoing service work.

3. Data

3.1 Overview

The "Store Work Order" feature provides a dedicated view within the Lumi ERP system to track and manage stock orders specifically linked to service work orders. This tool allows staff to search, filter, and monitor the status of inventory movements associated with service tasks, ensuring that parts and materials are accounted for from the warehouse to the store.

3.2 Step-by-Step Flow

1. Initiate Search: The user enters criteria into the search toolbar (such as specific order codes, date ranges, store/warehouse locations, or status).
2. Apply Filters: The system automatically scopes the search to "service work orders" and applies any additional filters provided by the user.
3. Data Retrieval: The system queries the inventory database to find all matching stock orders.
4. Information Consolidation: The system gathers related details, including the names of the store, warehouse, and the user who last updated the record.
5. Display Results: The retrieved data is presented in a table, where each row represents a stock order.
6. Navigation: Users can click on links within the table to open the specific stock order or the original service work order for further details.

3.3 Key Concepts

- Stock Order: A record tracking the movement or request of inventory items.
- Service Work Order: The specific service-related task that triggered the need for inventory.
- Workflow State: The current status of the order (e.g., pending, in progress, or completed).
- Reference Path: A direct link that allows users to jump from the inventory list back to the original service request.
-

Updater: The individual user responsible for the most recent change to the order record.

3.4 Business Value

This feature streamlines inventory management by centralizing all stock-related activities tied to service work. By providing clear visibility into order statuses, locations, and associated service tasks, it reduces manual tracking efforts, minimizes errors in inventory allocation, and ensures that service teams have the materials they need to complete their work on time.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Stock Order Service Orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Stock Order - Service Orders" feature provides a dedicated view within the Inventory module for tracking stock orders specifically linked to service orders. This interface allows users to monitor the status, financial details, and fulfillment progress of these orders in a clear, organized table format.

1.2 Step-by-Step Flow

1. Initial Load: When the page is opened, the system automatically fetches the most recent stock orders associated with service orders and displays them in the table.
2. Filtering: Users can refine the list using the Search Toolbar. By entering criteria such as specific order codes, date ranges, store or warehouse locations, or workflow statuses, the system updates the table to show only the relevant records.
3. Data Display: The table presents key information for each order, including dates, associated store/warehouse, current status, and financial amounts (order vs. received).
4. Navigation: Users can click on a specific Stock Order code to navigate directly to that order's detailed view, or click on a Service Order reference to view the original service request.

1.3 Key Concepts

- Stock Order: A formal request for inventory items, in this case, triggered by a service-related requirement.
- Service Order: The original customer or internal request that necessitated the stock order.
- Workflow State: The current progress of the order (e.g., pending, in-progress, completed), represented by a visual status badge.
- Search Toolbar: A set of controls that allows users to filter the list of orders by various parameters like date, location, or status.
- Order vs. Receive Amount: A comparison showing the total value requested versus the value of items actually received, helping to track fulfillment accuracy.

1.4 Business Value

This feature centralizes the management of service-related inventory, reducing the time spent searching for order status. By providing clear visibility into both the financial and logistical aspects of these orders, it enables staff to quickly identify pending deliveries, track fulfillment progress, and ensure that service orders are supported by the necessary inventory in a timely manner.

2. Logic

2.1 Overview

The Stock Order Service feature provides a dedicated view for managing inventory requests linked to service orders. It allows users to search, filter, and view a list of stock orders specifically related to service operations. The system automatically pulls this data, formats it for readability, and presents it in a clear table format for easy tracking of order status and financial details.

2.2 Step-by-Step Flow

1. Data Retrieval: When the page loads or a user performs a search, the system requests a list of stock orders filtered specifically for "service orders."
2. Filtering: Users can narrow down the list using various criteria, such as specific order codes, date ranges, store or warehouse locations, and current workflow status.
3. Data Mapping: The system takes the raw data from the database and assigns it to the appropriate columns in the table (e.g., mapping "created_at" to the "Date" column).
4. Formatting: The system applies display rules to make the data user-friendly:

* Monetary values (order and receive amounts) are formatted as currency.

* Dates are converted into a readable format.

* Statuses are displayed as visual badges.

5. Rendering: The final table is populated. If an order has not yet been received, the "Received At" field remains blank.
6. Navigation: Users can click on a Stock Order code to view its specific details or click on a Service Order code to navigate to the original service request.

2.3 Key Concepts

– Stock Order: A request for inventory items needed to fulfill a specific business requirement.

– Service Order: The originating request that triggered the need for stock; this feature links the two so users can see the relationship between the service and the inventory.

– Workflow State: The current stage of the order (e.g., pending, in-progress, completed), displayed as a status badge for quick identification.

– Reference Path: A direct link that allows users to jump from the stock order list to the original service order document.

2.4 Business Value

This feature improves operational efficiency by centralizing service-related inventory data. By providing a clear, searchable, and formatted view of stock orders, staff can quickly verify the status of parts or materials needed for service jobs. This reduces manual lookup time, helps prevent inventory delays, and ensures that financial tracking (order vs. received amounts) is accurate and transparent.

3. Data

3.1 Overview

The Stock Order Service feature provides a dedicated view within the Lumi ERP system to track inventory requests that originate specifically from service orders. This allows staff to easily monitor the lifecycle of stock items—from the initial request through to final receipt—ensuring that parts or materials needed for service tasks are accounted for and managed efficiently.

3.2 Step-by-Step Flow

1. Request Data: The system automatically queries the inventory database to retrieve all stock orders specifically tagged as "service orders."
2. Data Processing: The system organizes the raw information into a structured format, ensuring that details like order dates, store locations, and current status are correctly aligned.
3. Display in Table: The processed data is presented in a clear, row-by-row table format.
4. User Interaction: Users can click on specific stock order codes to view order details or click on service order references to navigate directly to the original service request.
5. Status Tracking: The system displays the current progress of the order (e.g., pending, received) and updates the "Received At" date once the inventory has been processed.

3.3 Key Concepts

- Stock Order: A formal request for inventory items to be moved or allocated to a specific location.
- Service Order: The originating request that triggered the need for stock, such as a repair or maintenance job.
- Workflow State: The current stage of the order, displayed as a status badge to help users quickly identify if an order is active, delayed, or completed.
- Reference Path: A direct digital link that allows users to jump from the inventory record back to the original service request for context.

3.4 Business Value

This feature bridges the gap between service operations and inventory management. By centralizing service-related stock orders, the business gains better visibility into supply chain needs, reduces the time spent manually

searching for order statuses, and ensures that service teams have the necessary parts available when they are needed. This leads to improved operational efficiency and more accurate inventory tracking.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Stock Order Sales Retail List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Stock Order Sales Retail List Page" is a dedicated view within the Lumi ERP system designed to help staff manage and track stock orders specifically related to retail sales. This page provides a clear, organized list of orders, allowing users to monitor the status of inventory moving between warehouses and stores to fulfill customer demand.

1.2 Step-by-Step Flow

1. Initial Loading: When you navigate to the page, the system automatically fetches the most recent retail stock orders.
2. Data Retrieval: The system pulls relevant order information, such as order codes, dates, store/warehouse locations, and current status.
3. Display: The information is presented in a structured table, making it easy to compare order amounts against what has actually been received.
4. Filtering: You can use the search toolbar to narrow down the list. You can filter by specific order numbers, date ranges, store or warehouse locations, and current workflow status to find exactly what you need.
5. Refining Results: Once you apply your filters and click "Search," the table updates to show only the records that match your criteria.

1.3 Key Concepts

- Stock Order: A formal request for inventory movement, specifically triggered by retail sales or e-commerce activity.
- Workflow State: The current stage of an order (e.g., pending, in-transit, or received), which helps staff understand if an order requires immediate attention.
- Search Toolbar: A set of controls that allows users to filter the list of orders by various criteria, such as date, location, or status, to improve visibility.
- Order vs. Received Amount: A comparison feature that shows the total quantity requested versus the quantity that has arrived, helping to identify discrepancies or partial shipments.

1.4 Business Value

This feature centralizes retail-related inventory management, reducing the time staff spend searching for order information. By providing real-time visibility into the status of stock orders—from the moment they are created until

they are received—the system helps prevent stockouts, improves the accuracy of inventory records, and ensures that retail stores are properly stocked to meet customer demand.

2. Logic

2.1 Overview

The Sales Retail Stock Order List page provides a centralized view for tracking inventory movements specifically related to retail sales. This feature automatically retrieves and displays relevant stock orders, allowing staff to monitor the status of orders originating from retail sales or shipping-related sales activities.

2.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically triggers a request to fetch the latest stock order data.
2. Data Retrieval: The system requests only "sales_retail" type orders from the database, retrieving them in batches of 20 to ensure optimal performance.
3. Filtering: The system automatically filters the retrieved list to include only orders specifically marked as "sale" or "shipping_sale," ensuring that unrelated stock movements are excluded.
4. Data Mapping: The system organizes the filtered data into a clear, readable format, matching specific order details (such as reference codes, dates, store/warehouse locations, and current status) to the corresponding columns in the user interface.
5. Display: The final, organized list is presented to the user in the Sales Retail Stock Order table.

2.3 Key Concepts

- Stock Order: A formal request to move inventory between locations, in this case, triggered by retail sales activity.
- Source Type: A classification that identifies the origin of the order (e.g., a standard sale or a shipping-based sale), used here to ensure only relevant retail data is shown.
- Workflow State: The current status of an order (e.g., pending, in-transit, or completed), which helps users understand where an order is in the fulfillment process.
- Pagination: The practice of loading data in smaller chunks (20 items at a time) to keep the page responsive and easy to navigate.

2.4 Business Value

This feature streamlines retail inventory management by providing a dedicated, filtered view of sales-related stock orders. By automating the retrieval and organization of this data, it reduces manual effort for staff, minimizes

the risk of viewing irrelevant information, and provides real-time visibility into the status of retail-driven inventory movements, ultimately supporting more efficient order fulfillment.

3. Data

3.1 Overview

The Sales Retail Stock Order List page provides a centralized view for tracking inventory movements specifically related to retail sales. This feature automatically retrieves and displays a list of stock orders that originated from retail sales or shipping sales, allowing staff to monitor the status, timing, and quantities of these orders in one place.

3.2 Step-by-Step Flow

1. Page Initialization: When you open the Sales Retail Stock Order page, the system automatically triggers a request to fetch the relevant order data.
2. Data Retrieval: The system filters the inventory database to find only "sales retail" stock orders that originated from a sale or shipping sale. It retrieves these in batches of 20 records at a time.
3. Data Processing: The system takes the raw order information and organizes it into a clear, readable format suitable for the table view.
4. Display: The processed information—including order references, store and warehouse locations, dates, current status, and quantities—is populated into the table for your review.

3.3 Key Concepts

- Sales Retail Stock Order: A specific type of inventory request created to fulfill a retail sale or a shipping-based sale.
- Workflow State: The current status of the order (e.g., pending, in progress, or completed), which helps you track where the order is in the fulfillment process.
- Order vs. Received Amount: A comparison of the quantity originally requested versus the quantity actually received, helping you identify discrepancies or partial shipments.
- Reference Codes: Unique identifiers for both the stock order itself and the original sale, allowing you to easily cross-reference the inventory movement with the actual customer transaction.

3.4 Business Value

This feature improves operational efficiency by providing a dedicated workspace for retail inventory management. By filtering out irrelevant data and presenting only retail-specific sales orders, staff can quickly identify which orders

are due, track their progress through the workflow, and verify that the correct amount of stock has been received. This reduces manual searching and helps ensure that retail sales are fulfilled accurately and on time.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Return (Fixed Asset)

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Purchase Return (Fixed Asset)" feature provides a centralized dashboard for managing the return of fixed assets to suppliers. This screen allows users to view a list of all existing return records, filter them by specific criteria, and easily navigate to detailed information for any individual return.

1.2 Step-by-Step Flow

1. Access the View: The user navigates to the Inventory section and selects the "Fixed Asset" tab to view the list of purchase returns.
2. Apply Filters: The user can narrow down the list by entering a specific Document Number, selecting a date range (From/To), choosing a supplier, or filtering by the current status (e.g., Draft, Approved).
3. Execute Search: Once the desired filters are set, the user clicks the "Search" button to refresh the table with the relevant records.
4. Review Data: The system displays a table showing key details for each return, including the document number, important dates (creation, sending, and approval), the supplier name, and the current status.
5. Navigate to Details: If the user needs to see more information about a specific return, they can click on the "Document Number" link to open the full details page for that record.
6. Manage Pagination: If there are many records, the user can use the pagination controls at the bottom of the screen to browse through the list in groups of 20.
7. Create New Return: If a new return needs to be initiated, the user can click the "New Purchase Return" button to be redirected to the creation page.

1.3 Key Concepts

- Document Number: A unique, system-generated identifier for each return record that serves as the link to view more details.
- Status Badge: A visual indicator showing the current lifecycle stage of a return, such as Draft, Sent, Approved, or Cancelled.
- Filter Bar: A set of search tools that allows users to find specific records without needing to scroll through the entire list.
- Pagination: A navigation tool that breaks large lists into manageable pages (20 records per page) to ensure the screen remains easy to read.

1.4 Business Value

This feature streamlines the fixed asset return process by providing a clear, organized view of all return activities. By enabling quick filtering and easy access to document details, it reduces the time spent searching for records and helps staff maintain accurate tracking of asset returns, ensuring that the status of every return is transparent and up-to-date.

2. Logic

2.1 Overview

This feature provides an automated view of "Purchase Returns" for fixed assets within the Lumi ERP system. When a user navigates to the Purchase Return page, the system automatically verifies their identity and immediately displays a list of all existing return records without requiring the user to manually trigger a search.

2.2 Step-by-Step Flow

1. Security Check: As soon as the page loads, the system checks if the user is logged in. If the user is not authorized, they are automatically redirected to the login screen.
2. Data Retrieval: Once the user is verified, the system automatically requests the list of purchase returns from the database.
3. Data Mapping: The system organizes the raw data into a readable table format, matching specific internal records (such as document codes, dates, and status) to the corresponding columns in the user interface.
4. Display: The final list is rendered on the screen, providing the user with an immediate overview of all purchase return activity.

2.3 Key Concepts

- Authentication: A security step that ensures only logged-in users can view sensitive inventory data.
- Automated Loading: A user-experience feature that populates the screen with data immediately upon arrival, removing the need for manual search actions.
- Data Mapping: The process of translating technical database information into clear, labeled columns that are easy for staff to read and understand.

2.4 Business Value

This feature improves operational efficiency by providing instant visibility into fixed asset returns. By automating the data retrieval process, staff members save time and reduce manual effort, allowing them to monitor the status of returns—such as when they were created, sent, or approved—without unnecessary clicks or delays.

3. Data

3.1 Overview

The Purchase Return (Fixed Asset) feature provides a centralized view for tracking the return of company assets to suppliers. This tool allows your team to monitor the lifecycle of a return—from its initial creation to its final approval—ensuring that all asset-related returns are properly documented and accounted for within the Lumi ERP system.

3.2 Step-by-Step Flow

1. Request Data: The system retrieves a list of all purchase returns specifically categorized as "Fixed Assets."
2. Data Retrieval: The system pulls the relevant records from the database, including details about the supplier and the current status of the return.
3. Information Mapping: The system organizes the raw data into a clear, readable format for your dashboard, matching specific details to the appropriate columns in your view.
4. Display: The final list is presented in the interface, showing the document number, key dates (creation, submission, and approval), the supplier involved, and the current status of the return.

3.3 Key Concepts

- Fixed Asset: A long-term physical asset (such as machinery, equipment, or furniture) that the company has purchased and may need to return to a supplier.
- Purchase Return: The formal process of sending an item back to a supplier, which requires tracking to ensure the company receives credit or a replacement.
- Status Tracking: A way to see exactly where a return is in the process, such as whether it is still being prepared, has been sent, or has been officially approved.
- Reference Code: A unique identifier assigned to each return document, making it easy to search for and reference specific transactions.

3.4 Business Value

This feature improves inventory accuracy and financial oversight by providing a transparent audit trail for asset returns. By digitizing this process, your team can quickly identify the status of any return, reduce administrative errors, and ensure that the company’s fixed asset records remain up-to-date and accurate for reporting and accounting purposes.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Return Standard - Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Return Detail page provides a comprehensive view of a specific return transaction. It allows staff to review the status of a return, verify the items being sent back, and access related documentation—such as the original purchase order, invoice, and accounting records—all in one place.

1.2 Step-by-Step Flow

1. Loading Data: When you open the page, the system automatically retrieves the return details and the list of items associated with that specific return.
2. Navigation & Context: The page displays a top navigation bar and an inventory sub-menu (with the "Store" tab active) to help you maintain context within the system.
3. Workflow Tracking: A status tracker at the top shows the current stage of the return (Draft, Confirmed, Sent, or Approved). You can click on a new status to advance the workflow, which triggers a confirmation prompt to prevent accidental changes.
4. Reviewing Details: The header section displays key information, including the return number, date, total amount, and links to related records (Purchase Order, Invoice, Warehouse, and Supplier).
5. Item Verification: The items table lists every product included in the return, showing the quantity requested versus the quantity confirmed, along with pricing and the reason for the return.
6. Accounting & Reporting: You can view associated accounting journal entries and use the "Print" button to generate a hard copy of the return document for your records.
7. Returning to List: A "Back" button is available to quickly return you to the main Purchase Returns overview page.

1.3 Key Concepts

- Workflow Status: The lifecycle stages of a return (Draft to Approved) that ensure the return process follows company policy.
- Reference Links: Quick-access shortcuts that allow you to jump directly to related documents like the original Purchase Order or Invoice without searching for them manually.
- Return Items Table: A detailed breakdown of the inventory being returned, which helps in reconciling what was requested versus what was actually processed.
- Confirmation Prompt: A safety feature that requires you to verify a status change before the system updates the record, reducing the risk of errors.

1.4 Business Value

This feature centralizes all critical information regarding a purchase return, reducing the time staff spend toggling between different screens to find related invoices or purchase orders. By providing a clear, step-by-step workflow tracker and easy access to accounting journals, the page ensures that inventory returns are processed accurately, transparently, and in alignment with the company's financial records.

2. Logic

2.1 Overview

The Franchise Purchase Return Details feature provides a comprehensive view of a specific return transaction. When a user opens the details page, the system automatically gathers all relevant information—including the main return summary, the specific items being returned, and links to related business documents—to provide a complete snapshot of the return process.

2.2 Step-by-Step Flow

1. Initialization: When a user navigates to the Purchase Return details page, the system triggers a request to retrieve the specific record.
2. Data Retrieval: The system fetches the main return header (containing dates, status, and totals) and the list of individual items associated with that return.
3. Context Enrichment: The system looks up related information, such as the specific franchise name and the original purchase order number, to ensure the page displays human-readable names rather than just internal ID codes.
4. Mapping and Assembly: The system compiles all gathered data—including administrative notes, audit timestamps (created/updated/sent), and links to related invoices, warehouses, and suppliers—into a single, organized view.
5. Display: The final, consolidated information is presented to the user, allowing them to review the return status and details.

2.3 Key Concepts

- Purchase Return Header: The primary record containing high-level information about the return, such as the date, total amount, and current workflow status.
- Return Items: The specific list of products included in the return, detailing quantities, pricing, and the reason for the return.
-

Workflow Status: A tracker that displays the current stage of the return (e.g., Draft, Confirmed, Sent, or Approved) to keep users informed of the process.

- Reference Links: Direct connections to related entities like the supplier, warehouse, or original invoice, allowing users to navigate quickly to supporting documentation.
- Audit Trail: A set of timestamps and user identifiers that track when the return was created, updated, or sent, ensuring accountability and transparency.

2.4 Business Value

This feature centralizes all critical information regarding a franchise purchase return into one screen. By automating the collection of related data (like supplier links and original purchase order details), it eliminates the need for manual cross-referencing. This improves operational efficiency, reduces the risk of errors during the review process, and provides clear visibility into the status of inventory returns across the franchise network.

3. Data

3.1 Overview

The Franchise Purchase Return Details feature provides a comprehensive view of individual purchase returns initiated by a franchise. This page acts as a central hub where staff can review the specific details of a return, including which items were sent back, the reasons for the return, and the financial impact of the transaction. By consolidating information from the original purchase order and the return record, this feature ensures transparency and accuracy in inventory management.

3.2 Step-by-Step Flow

1. Request Retrieval: The system receives a request to view a specific purchase return record.
2. Data Aggregation: The system gathers the main return information (such as the return date, status, and associated franchise) alongside the original purchase order reference.
3. Item Retrieval: The system pulls the list of all individual products included in that specific return, including the quantity, price, and the reason for each item's return.
4. Calculation: The system automatically calculates the total number of items returned and the total financial value of the return.
5. Display: The complete package of information—header details, itemized list, and financial summary—is presented to the user.

3.3 Key Concepts

-

Purchase Return: A formal record documenting items sent back by a franchise to the supplier or central warehouse.

- Return Header: The top-level information for a return, such as the return ID, the date it occurred, the status of the return, and the franchise involved.
- Line Items: The individual products listed within a return, detailing exactly what was returned, how much of it, and why (e.g., damaged, expired, or incorrect item).
- Financial Summary: An automated calculation that provides the total value of the return based on the quantity and price of the items involved.

3.4 Business Value

- Operational Efficiency: Staff can quickly verify return details without manually cross-referencing multiple documents or systems.
- Improved Accuracy: Automated calculations for total return values reduce the risk of human error during financial reconciliation.
- Better Decision Making: By capturing the "reason code" for each returned item, management can identify trends in product quality or ordering issues, helping to reduce future returns.
- Audit Readiness: Having a clear, consolidated view of every return ensures that the business maintains a reliable paper trail for inventory and accounting purposes.

BUSINESS REQUIREMENTS DOCUMENT

Suppliers List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Suppliers List page provides a centralized dashboard for managing your organization's supplier database. It allows users to view, search, and filter supplier records, as well as navigate to specific supplier details for further management. The page is designed to help you quickly locate supplier information and perform essential administrative tasks like adding new suppliers or updating existing ones.

1.2 Step-by-Step Flow

1. Initial Load: When you first open the page, the system automatically displays a list of external suppliers.
2. Navigation: You can toggle between "Supplier" (external) and "Internal" views using the navigation tabs to switch the list content.
3. Filtering: You can narrow down the list by entering specific criteria into the filter bar, such as Supplier Code, Name, Contact Name, Phone, or Status (Active/Inactive).
4. Search: After entering your criteria, click the "Search" button to refresh the table with the filtered results.
5. Viewing Details: You can click on a supplier's Code or Name to be redirected to their specific detail page.
6. Managing Records:

* Click the "New Supplier" button to create a new entry.

* Click the "Edit" button on any row to update that supplier's information.

* Click the "Activate" or "Deactivate" button to change the status of a supplier record.

1.3 Key Concepts

- Supplier List: The primary table view that displays key supplier data, including contact information, tax details, and purchase order permissions.
- Filter Bar: A set of input fields that allows you to refine the list based on specific attributes, helping you find records faster.
- Internal vs. External: A categorization toggle that separates your internal suppliers from your external business partners.
- Pagination: A system feature that organizes large lists of suppliers into manageable pages to ensure the application remains fast and easy to navigate.
- Status Toggle: A quick-action feature that allows you to switch a supplier between "Active" and "Inactive" states directly from the list.

1.4 Business Value

This feature streamlines supplier management by providing a single, searchable interface. By allowing users to quickly filter and access supplier details, the page reduces the time spent searching for information. Additionally, the ability to manage supplier status and access edit/add functions directly from the list improves operational efficiency and ensures that your supplier database remains accurate and up-to-date.

2. Logic

2.1 Overview

The Suppliers List Page provides a centralized view for managing external business partners. This feature allows users to browse, search, and filter through the company's supplier database. The interface is designed to be intuitive, displaying key contact and operational details in a clean table format, while providing quick access to status management actions.

2.2 Step-by-Step Flow

1. Initial Load: When the page is first opened, the system automatically retrieves the first page of external suppliers.
2. Data Retrieval: The system fetches supplier records, excluding internal entities to ensure the list remains focused on external partners.
3. Search and Filter: Users can input search terms to narrow down the list by supplier name or code. The system updates the view based on these criteria.
4. Pagination: As the user navigates through the list, the system loads data in segments (pages) to maintain optimal performance.
5. Data Formatting: The system processes raw supplier information into a user-friendly table, combining address and country details and determining the appropriate "Activate" or "Deactivate" button label based on the supplier's current status.
6. Interaction: Users can perform actions directly from the table, such as editing details or toggling the active status of a supplier.

2.3 Key Concepts

- Supplier List: A comprehensive table displaying essential information including contact details, tax numbers, and purchase order permissions.
- Search/Filter: Tools that allow users to quickly locate specific suppliers by name or unique identification code.
- Pagination: A method of breaking the supplier list into manageable pages to ensure the page remains fast and easy to read.

- Status Management: A dynamic feature that allows users to toggle a supplier between "Active" and "Inactive" states directly from the list.
- External Supplier: The scope of the list is limited to external partners, ensuring internal records do not clutter the view.

2.4 Business Value

This feature streamlines procurement and vendor management by providing a single, searchable source of truth for all external suppliers. By automating the display of contact and operational data, it reduces the time staff spend searching for vendor information. Furthermore, the ability to manage supplier status directly from the list improves operational efficiency and ensures that only authorized vendors are available for purchase orders.

BUSINESS REQUIREMENTS DOCUMENT

Supplier - New Supplier Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Supplier" page is a dedicated interface within the Lumi ERP system designed to capture all necessary information to register a new supplier. This page ensures that essential business data—such as contact details, tax information, and credit terms—is accurately recorded and linked to the correct financial accounts before being saved to the system.

1.2 Step-by-Step Flow

1. Data Entry: The user fills out the form, which includes mandatory fields (marked with an asterisk) such as Supplier Name, Contact Person, Phone Number, Address, Country, Credit Terms, and Sales Tax rules.
2. Optional Information: The user may provide additional details, including the supplier code, tax/registration numbers, communication details (fax, mobile, email), credit limits, and internal notes.
3. Configuration Settings: The user sets operational flags, such as whether the supplier is currently active, if they are an internal entity, and if they are permitted to receive store-level purchase orders.
4. Financial Mapping: The user selects the appropriate financial accounts for invoices, credit notes, down payments, and deposits to ensure proper accounting integration.
5. Validation: The system monitors the form in real-time. The "Save" button remains disabled until all mandatory fields are correctly completed.
6. Submission: Upon clicking "Save," the system packages the entered data into a structured format and sends it to the ERP database. If the user decides not to proceed, they can click "Cancel" to exit the page without saving.

1.3 Key Concepts

- Mandatory Fields: Essential information required by the system to ensure every supplier record is complete and functional.
- Real-time Validation: A feature that checks the form as you type, preventing submission if required information is missing or incomplete.
- Financial Account Mapping: The process of linking a supplier to specific accounting categories (like invoices or deposits), which automates how the system handles future transactions with that supplier.
- Operational Flags: Checkboxes that define the supplier's status and permissions, such as whether they are "Active" or authorized to interact with specific store purchase orders.

1.4 Business Value

This feature streamlines the onboarding process for new suppliers by providing a structured, error-proof interface. By enforcing data entry at the point of creation and linking suppliers directly to the correct financial accounts, the system reduces manual data entry errors, ensures consistent accounting practices, and allows for immediate, seamless integration of the new supplier into the broader procurement and purchasing workflows.

2. Logic

2.1 Overview

The "New Supplier" page allows users to register a new supplier in the Lumi ERP system. This feature provides a structured form to capture essential business details—such as contact information, tax identifiers, credit terms, and accounting settings—ensuring that all necessary data is accurately recorded and saved to the system database.

2.2 Step-by-Step Flow

1. Data Entry: The user fills out the "New Supplier" form with relevant details, including the supplier's name, contact information, financial settings, and internal notes.
2. Submission: The user clicks the "Save" button to finalize the entry.
3. Processing: The system triggers a loading state to indicate that the information is being processed.
4. Data Mapping: The system automatically translates the information entered in the form into the specific format required by the internal database.
5. Validation & Storage: The system sends the formatted data to the server.

- If the data is successfully saved, the system displays a confirmation message to the user.
- If an error occurs (e.g., missing required information), the system notifies the user that the save was unsuccessful.

6. Completion: The loading state is removed, returning the user to the interface.

2.3 Key Concepts

- Supplier Profile: The collection of business information (contact, tax, and financial) required to manage a relationship with a vendor.
- Data Mapping: The behind-the-scenes process that ensures the information typed into the form fields is correctly labeled and organized for the system's database.
- Loading State: A visual indicator (such as a spinner or disabled button) that prevents duplicate submissions while the system is busy saving data.
- Feedback Notification: Alerts provided to the user to confirm that a supplier was created successfully or to warn them if an issue occurred during the process.

2.4 Business Value

This feature streamlines the onboarding of new vendors by providing a centralized, standardized entry point. By capturing comprehensive financial and operational data at the point of creation, the system ensures that accounting and procurement teams have the accurate information needed to process invoices, manage credit limits, and maintain tax compliance from day one.

3. Data

3.1 Overview

The New Supplier Page is a dedicated interface within the Lumi ERP system designed to streamline the onboarding of new business partners. This feature allows users to input essential contact and identification details for a supplier, ensuring that all necessary information is captured accurately and stored securely in our database to support ongoing procurement and financial operations.

3.2 Step-by-Step Flow

1. Data Entry: The user enters the supplier's name, tax identification number, email address, phone number, and physical address into the system.
2. Uniqueness Check: The system automatically verifies that the provided tax identification number is not already associated with an existing supplier to prevent duplicate records.
3. Record Creation: Once the information is validated, the system assigns a unique internal identifier and a timestamp to the entry.
4. Status Assignment: The system automatically sets the supplier's status to "Active," making them immediately available for use within the ERP.
5. Confirmation: The completed supplier profile is saved to the database, and the system confirms the successful creation of the record.

3.3 Key Concepts

- Tax Identification Number: A unique government-issued identifier used to distinguish one business entity from another for tax and regulatory purposes.
- Unique Identifier: A system-generated code that ensures every supplier record is distinct and can be referenced accurately across the platform.
- Active Status: A default setting applied to new suppliers that indicates they are ready to be engaged for business transactions immediately upon registration.

3.4 Business Value

This feature provides a standardized and reliable method for adding new suppliers to the Lumi ERP. By automating the uniqueness check for tax IDs, the system prevents data duplication and maintains high data integrity. This efficiency reduces manual administrative work and ensures that procurement teams have immediate access to accurate supplier information, ultimately accelerating the onboarding process and improving operational accuracy.

BUSINESS REQUIREMENTS DOCUMENT

Suppliers Details Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier Details Page provides a centralized, read-only view of all information related to a specific supplier within the Lumi ERP system. This page allows users to quickly review contact information, credit terms, operational settings, pricing, and historical audit logs for a selected supplier. It also includes navigation tools to return to the main supplier list or transition to an edit mode if updates are required.

1.2 Step-by-Step Flow

1. Loading Data: When a user selects a supplier, the system retrieves all relevant records from the database. A loading indicator is shown while this data is being fetched.
2. Header Display: The page displays the supplier's name at the top, along with a "Back" button to return to the supplier list and an "Edit" button to modify the record.
3. Navigation: A tabbed menu allows the user to switch between the current "Suppliers" view, "Products," and "History."
4. Information Sections: The page organizes data into logical groups:

* Details: Contact information, identification codes, and address.

* Credit Terms: Financial limits and payment conditions.

* Settings: Operational flags (e.g., active status, internal supplier status) and tax settings.

* Prices: The specific price list assigned to the supplier.

* Notes: Bank account details and any additional free-text notes.

* Changes: An audit trail showing when the record was created or updated and by whom.

5. Error Handling: If the system cannot find the requested supplier, a "Supplier not found" message is displayed.

1.3 Key Concepts

- Supplier Record: The complete profile of a business partner, containing all necessary data for procurement and accounting.
- Audit Trail: A record of "Changes" (created/updated timestamps and user names) that ensures accountability and transparency for data modifications.
- Operational Flags: Settings that define how the system interacts with the supplier, such as whether they are currently active or if they are permitted to use store purchase orders.
-

Read-Only View: The primary state of the page, designed for safe data review without the risk of accidental changes.

1.4 Business Value

This feature improves operational efficiency by providing procurement and finance teams with a "single source of truth" for supplier data. By consolidating contact, financial, and audit information into one organized view, users can make faster, more informed decisions regarding purchasing and vendor management without needing to navigate through multiple screens or external documents.

2. Logic

2.1 Overview

The Supplier Details Page is a secure view within the Lumi ERP system that provides a comprehensive summary of a specific supplier's information. When a user navigates to this page, the system automatically verifies their identity and retrieves the relevant supplier data to display in an organized, easy-to-read format.

2.2 Step-by-Step Flow

1. Authentication Check: Upon loading the page, the system verifies that the user is currently logged in. If the user is not authenticated, they are automatically redirected to the Login Page.
2. Data Retrieval: Once authenticated, the system requests the specific details for the supplier identified in the web address.
3. Error Handling: If the requested supplier cannot be found in the system, the page will display a "not found" state to inform the user.
4. Information Mapping: If the data is successfully retrieved, the system organizes the information into specific sections on the page, such as contact details, credit terms, administrative notes, and account settings.

2.3 Key Concepts

- Authentication: A security check that ensures only logged-in users can view sensitive supplier information.
- Data Mapping: The process of taking raw information from the system database and placing it into the correct, labeled sections on the user interface.
- Supplier Record: The complete profile of a supplier, including contact info, financial terms (like credit limits), and internal administrative notes.
- Not Found State: A user-friendly message displayed when a user attempts to access a supplier record that does not exist or has been removed.

2.4 Business Value

This feature ensures that staff members have quick, reliable access to critical supplier information—such as payment terms, contact details, and account status—in one centralized location. By automating the retrieval and organization of this data, the system reduces manual lookup time and ensures that users are always viewing the most up-to-date information, which supports better decision-making and more efficient supplier management.

3. Data

3.1 Overview

The Supplier Details Page is a centralized dashboard within the Lumi ERP system designed to provide a comprehensive view of a specific supplier's profile. This page aggregates all relevant information—ranging from contact details and financial terms to internal settings and administrative history—into a single, organized interface, allowing users to quickly access and verify supplier data.

3.2 Step-by-Step Flow

1. Request Initiation: When a user selects a specific supplier, the system retrieves the complete profile information for that supplier from the database.
2. Data Organization: The system processes the raw supplier data and categorizes it into logical groups to ensure the information is easy to read.
3. Display Generation: The organized data is presented on the Supplier Details Page, structured into the following sections:

* Header: Displays the primary name of the supplier.

* Details Section: Shows contact information, including email, phone number, and physical address.

* Credit Terms Section: Outlines the financial agreements, such as credit limits and payment terms.

* Changes Section: Provides an audit trail showing when the record was created or updated, and by whom.

* Note Section: Displays internal bank account details and any additional notes regarding the supplier.

* Settings Section: Shows operational flags, such as whether the supplier is active, if they are an internal partner, and if they are authorized for store purchase orders, along with tax information.

* Prices Section: Identifies the specific price list assigned to the supplier.

3.3 Key Concepts

– Supplier Profile: A complete digital record containing all contact, financial, and operational information for a business partner.

–

Audit Trail: A record of administrative changes that tracks when information was last modified and which user performed the update.

- Operational Flags: Status indicators that determine how the system interacts with a supplier, such as whether they are currently active or permitted to receive purchase orders.
- Financial Terms: The agreed-upon credit limits and payment schedules that govern the business relationship with the supplier.

3.4 Business Value

This feature improves operational efficiency by eliminating the need to search through multiple screens or documents to find supplier information. By providing a structured, "single source of truth" for each supplier, the page helps staff make faster, more informed decisions regarding procurement, payments, and account management. Additionally, the inclusion of an audit trail and clear operational settings ensures better data accuracy and accountability across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Suppliers Edit Suppliers Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Edit Supplier" page allows users to view and update existing supplier information within the Lumi ERP system. The page is designed to be intuitive, organizing complex supplier data into logical sections—such as contact details, credit terms, pricing, and accounting settings—so that users can easily manage and maintain accurate records.

1.2 Step-by-Step Flow

1. Loading Data: When the page opens, the system automatically retrieves the specific supplier's information based on the unique ID provided in the web address.
2. Displaying Information: Once the data is retrieved, the page populates several sections (cards) with the current information, including contact details, credit terms, pricing, notes, and accounting settings.
3. Editing: Users can modify any of the fields within these sections. The system ensures that the interface remains responsive while the user makes changes.
4. Saving Changes: When the user clicks the "Save" button, the system validates the information and sends an update request to the server.
5. Confirmation: Upon a successful update, the system displays a confirmation message and refreshes the page with the latest saved data. If an error occurs, the system displays the specific issue while keeping the user's changes intact so they can correct them.
6. Canceling: If the user decides not to save their changes, they can click the "Cancel" button to discard their edits and return to the previous screen.

1.3 Key Concepts

- Supplier Profile: The complete set of information regarding a vendor, including their contact details, financial terms, and accounting configurations.
- Data Validation: A built-in check that ensures all required information is correctly entered before the system accepts the changes.
- Form State: The temporary "in-progress" version of the supplier data that the user is currently editing before it is officially saved to the system.
- API Integration: The background communication between the user's screen and the central database that ensures data is fetched and updated securely.

1.4 Business Value

This feature streamlines supplier management by providing a centralized, user-friendly interface for maintaining vendor data. By allowing users to easily update credit terms, pricing, and accounting settings, the business can ensure that its financial records remain accurate and up-to-date, reducing the risk of errors in purchasing and accounting workflows. The clear, sectioned layout minimizes the time spent on administrative tasks and improves overall data integrity.

2. Logic

2.1 Overview

The "Edit Supplier" feature allows users to view and update existing supplier information within the Lumi ERP system. When a user navigates to the edit page for a specific supplier, the system automatically retrieves the current record and populates the form fields. Users can then modify details—such as contact information, credit terms, pricing, and accounting settings—and save their changes to update the system.

2.2 Step-by-Step Flow

1. Loading the Page: When the page opens, the system identifies the specific supplier using a unique ID from the web address.
2. Data Retrieval: The system fetches the current supplier data. If the user is not logged in, they are redirected to the login screen; if the supplier cannot be found, an error message is displayed.
3. Form Population: Once the data is successfully retrieved, the system maps the information into the appropriate sections (Details, Credit Terms, Prices, Notes, and Settings) so the user can see the current values.
4. Editing: The user makes necessary changes to any of the fields across the various cards.
5. Saving Changes: When the user clicks "Save," the system validates the information and sends the updated data to the server.
6. Confirmation: Upon a successful update, the system displays a success notification and refreshes the form with the latest data. If an error occurs, the system displays the specific issue while keeping the user's changes intact so they can correct them and try again.

2.3 Key Concepts

- Supplier Record: The complete set of information regarding a vendor, including contact details, financial terms, and accounting configurations.
- Mapping: The process of taking raw data from the system and placing it into the correct, user-friendly fields on the screen.
-

Validation: A check performed by the system to ensure that all required information is provided and correctly formatted before saving.

– Error Handling: The mechanism that ensures the user is notified if something goes wrong (e.g., a missing supplier or a validation error) and prevents data loss by keeping the form populated after a failed save attempt.

2.4 Business Value

This feature ensures that supplier data remains accurate and up-to-date, which is critical for maintaining smooth procurement and financial operations. By providing a structured, easy-to-use interface for editing, the system reduces the risk of manual entry errors and ensures that accounting and credit settings are always aligned with the latest business agreements.

3. Data

3.1 Overview

The "Edit Supplier" feature provides a centralized interface for managing existing supplier information within the Lumi ERP system. This page allows users to view and update a supplier's contact details, credit terms, pricing configurations, internal notes, and accounting settings. The system ensures that data is accurately retrieved, displayed, and saved, maintaining consistency across the platform.

3.2 Step-by-Step Flow

1. Page Initialization: When a user navigates to the Edit Supplier page, the system identifies the specific supplier using a unique ID from the web address.
2. Data Retrieval: The system automatically fetches the current supplier’s profile from the database.
3. Form Population: Once the data is retrieved, the system maps the information into the appropriate sections of the page (Details, Credit Terms, Prices, Notes, and Settings) so the user can see the current values.
4. User Modification: The user updates the necessary fields across the various cards on the page.
5. Saving Changes: When the user clicks the "Save" button, the system validates the input and sends only the modified information to the server.
6. Confirmation and Error Handling:

– If the update is successful, the system displays a confirmation message and refreshes the form with the latest data.

– If an error occurs, the system preserves the user's current input, displays an error message, and re-enables the "Save" button so the user can correct the issue and try again.

3.3 Key Concepts

- Supplier Profile: The complete set of information regarding a supplier, including contact info, financial terms, and accounting mappings.
- Form Mapping: The process of taking raw data from the database and placing it into the correct fields on the user interface, and vice versa.
- Partial Update: A method of saving where only the fields that were actually changed by the user are sent to the server, which improves efficiency and prevents accidental overwrites.
- Accounting Mappings: Specific settings that link a supplier to the correct financial accounts (such as inventory purchases or deposits) to ensure accurate bookkeeping.

3.4 Business Value

This feature streamlines supplier management by providing a single, reliable source of truth for all supplier-related data. By automating the retrieval and update process, it reduces manual data entry errors and ensures that financial and operational settings—such as credit limits and accounting codes—are always up to date. This allows procurement and finance teams to work more efficiently and maintain accurate records for all business transactions.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Product List Page

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Supplier Product List page provides a centralized view of all products associated with a specific supplier. This page allows users to easily browse, search, and filter a supplier's catalog, as well as view key details such as inventory tracking status and discount information.

1.2 Step-by-Step Flow

1. Page Initialization: When the page loads, the system automatically retrieves the full list of products for the selected supplier.
2. Displaying Information: The page displays the supplier's name at the top, followed by a table containing all relevant product data.
3. Filtering: Users can narrow down the list by entering specific criteria into the filter toolbar, including Product SKU, Product Name, or Supplier Discount.
4. Search Execution: Once the user clicks the "Search" button, the system updates the table to show only the products that match the entered filter criteria.
5. Navigation: Users can click on a product name or its SKU to be redirected to a dedicated page containing more detailed information about that specific item.

1.3 Key Concepts

- Filter Toolbar: A set of input fields that allows users to refine the product list based on specific attributes before triggering a search.
- Product Table: A structured list displaying product details, including row numbers, names, SKUs, discount percentages, and inventory tracking status.
- Inventory Tracking Indicator: A visual status (represented by a checkmark or an "x") that indicates whether the system is currently monitoring stock levels for a specific product.
- Read-Only Data: Most information on this page is for viewing purposes only, ensuring that the product list remains a reliable reference point for the user.

1.4 Business Value

This feature improves operational efficiency by providing procurement and inventory teams with a quick, searchable interface to manage supplier relationships. By consolidating product data, discounts, and inventory status into one view, users can make faster, more informed purchasing decisions and easily identify which products require active inventory monitoring.

2. Logic

2.1 Overview

The Supplier Product List feature provides a clear, organized view of all items associated with a specific supplier within the Lumi ERP system. When you navigate to a supplier's profile, the system automatically retrieves their product catalog and presents it in a user-friendly table, highlighting key purchasing information such as pricing, discounts, and inventory status.

2.2 Step-by-Step Flow

1. Request Initiation: When you open the product list page for a specific supplier, the system triggers a request to gather all relevant product data.
2. Data Retrieval: The system searches the database to find every product linked to that specific supplier.
3. Information Transformation: The raw data is processed and mapped into a readable format for the screen. This includes calculating any applicable discounts and determining the current inventory status.
4. Display: The final list is presented to you, showing the product name, SKU, discount percentage, and a visual indicator of whether the item is currently being tracked for inventory.

2.3 Key Concepts

- SKU: A unique identification code used to track individual products within the inventory.
- Supplier Discount: A calculated percentage representing any price reductions applied to a product based on supplier agreements.
- Inventory Tracking: A visual status indicator (represented by a checkmark or an 'X') that tells you if the system is actively monitoring the stock levels for that item.

2.4 Business Value

This feature streamlines procurement and supplier management by providing immediate visibility into a supplier's offerings. By automating the display of discounts and inventory status, users can make faster, more informed purchasing decisions without needing to manually cross-reference separate documents or spreadsheets. This ensures that your team always has the most accurate and up-to-date information when managing supplier relationships.

3. Data

3.1 Overview

The Supplier Product List feature provides a dedicated view within the Lumi ERP system to manage and review the catalog of items offered by a specific supplier. This page allows users to quickly browse, search, and access detailed information for any product associated with a chosen supplier, ensuring that procurement and inventory teams have accurate, up-to-date visibility into their supply chain.

3.2 Step-by-Step Flow

1. Supplier Selection: The user navigates to a specific supplier's profile, which triggers the system to load the associated product catalog.
2. Data Retrieval: The system fetches the list of products linked to that supplier, automatically organizing them alphabetically by name.
3. Pagination: To ensure the page remains fast and easy to navigate, the system displays products in manageable groups (pages). It calculates the total number of products available to provide accurate navigation controls for the user.
4. Detailed View: If a user needs more information on a specific item, they can select a product from the list to view its full details, including pricing, stock levels, and current status.

3.3 Key Concepts

- Product Catalog: A comprehensive list of all items provided by a specific supplier, including unique identifiers, pricing, and current availability.
- Pagination: A method of breaking down a large list of products into smaller, manageable pages to improve system performance and user experience.
- Stock Level: The current quantity of a specific product held in inventory, helping users make informed purchasing decisions.
- Product Status: An indicator of whether a product is currently active or available for order within the system.

3.4 Business Value

This feature streamlines the procurement process by centralizing supplier-specific data. By providing a clear, organized view of product catalogs, the system reduces the time spent searching for item information, minimizes errors in ordering, and allows teams to monitor stock levels proactively. This leads to better supplier management and more efficient inventory control across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - History Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier History page provides a transparent audit trail for any changes made to a supplier's profile. This feature allows users to view a chronological list of updates, including who made the change, when it occurred, and what specific details (such as contact information, credit terms, or tax details) were modified.

1.2 Step-by-Step Flow

1. Authentication Check: When you navigate to the page, the system first verifies that you are logged in. If your session has expired or you are not logged in, you will be automatically redirected to the login screen.
2. Data Retrieval: Once authenticated, the system fetches the complete change history for the specific supplier.
3. Error Handling: If the supplier cannot be found, the system will display a notification informing you that the history is unavailable.
4. Displaying Information: The page displays the current supplier's name at the top. Below this, a table lists every recorded change, showing the date of the update, the user who performed it, and the updated values for all relevant supplier fields.
5. User Navigation: If you need to see more information about the person who made a specific change, you can click on their name in the "Updated By" column to view their user profile.

1.3 Key Concepts

- Audit Log: A historical record of all modifications made to a supplier's information, ensuring accountability and data accuracy.
- Authentication: A security step that ensures only authorized users can view sensitive supplier history data.
- Change Tracking: The system captures specific data points—such as address, phone number, email, and credit limits—every time an update is saved, allowing you to see exactly what changed and when.

1.4 Business Value

- Accountability: By tracking who updated supplier details and when, your team can easily identify the source of any data changes.
- Data Integrity: Having a clear history of modifications helps in auditing supplier records and resolving discrepancies in contact or financial information.
- Operational Efficiency: Instead of guessing when a supplier's credit terms or contact details were last changed, staff can instantly verify the information, reducing the time spent on manual record-keeping or internal inquiries.

2. Logic

2.1 Overview

The Supplier History page provides a transparent audit trail for each supplier within the Lumi ERP system. This feature allows authorized users to view a chronological list of all modifications made to a supplier's profile, ensuring accountability and providing a clear record of how and when supplier information has changed over time.

2.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the Supplier History page, the system first verifies that the user is logged in. If the session is invalid or missing, the user is automatically redirected to the login screen.
2. Data Retrieval: Once authenticated, the system attempts to fetch the complete change history for the specific supplier. If the supplier cannot be found, the system displays a "Not Found" message.
3. Sorting and Organization: The system organizes the history records, placing the most recent changes at the top of the list.
4. Header Update: The page header is automatically updated to display the supplier's current name, pulled from the most recent record.
5. Table Population: The system populates the history table with detailed information, including the date of the change, the person who made the update, and the specific values for fields like contact details, tax information, and credit terms.

2.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific supplier's data.
- Authentication: The security process that ensures only logged-in users can access sensitive supplier history information.
- Data Mapping: The process of taking raw system information and presenting it in a user-friendly table format, ensuring that fields like "Credit Limit" or "Tax No." are clearly labeled and easy to read.
- Change Log: A list of modifications that tracks what was changed, who changed it, and when the change occurred.

2.4 Business Value

- Accountability: By tracking who updated supplier information and when, the organization can maintain better oversight of data changes.
-

Data Integrity: Users can easily verify the accuracy of supplier details by reviewing the history of updates, helping to identify and correct potential errors.

- Operational Efficiency: Instead of searching through manual records or emails, staff can instantly access a digital history of changes, saving time during audits or when investigating discrepancies in supplier data.

3. Data

3.1 Overview

The Supplier History feature provides a transparent audit trail for all changes made to a supplier's profile. This page allows you to view a chronological record of updates, showing exactly what information was modified, who performed the update, and when the change occurred. This ensures accountability and provides a clear reference for how supplier data has evolved over time.

3.2 Step-by-Step Flow

1. Data Retrieval: The system fetches the complete history of changes associated with a specific supplier.
2. Header Identification: The system identifies the most recent update to display the current supplier name at the top of the page for easy identification.
3. Data Mapping: Each individual change record is processed and organized into a structured table format.
4. Table Display: The table populates with the timestamp of the change, the name of the user who made the edit, and the specific values for all supplier fields (such as contact details, credit terms, and tax information) as they existed at that moment.

3.3 Key Concepts

- Audit Trail: A chronological record that tracks the history of changes to a specific supplier's profile.
- Change Log: The collection of historical data entries that detail what information was updated and by whom.
- Field Tracking: The specific supplier attributes being monitored, including contact information, registration numbers, and financial terms like credit limits.

3.4 Business Value

- Accountability: By logging who made each change, your team can easily identify the source of data updates, reducing errors and unauthorized modifications.
- Data Integrity: Having a clear history of changes helps in troubleshooting discrepancies in supplier information, such as unexpected changes to credit terms or contact details.
-

Operational Transparency: Provides a reliable reference point for auditors or managers to review the lifecycle of a supplier’s profile without needing to search through manual records or emails.

BUSINESS REQUIREMENTS DOCUMENT

Sales Ecommerce /sales/ecommerce

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Ecommerce Sales page provides a centralized dashboard for viewing and managing sales originating from your online channels. This feature allows staff to monitor order progress, filter sales by specific criteria (such as store location, customer, or status), and quickly navigate to detailed records for individual transactions, customers, or vehicles.

1.2 Step-by-Step Flow

1. Authentication Check: Upon loading the page, the system verifies your login session. If you are not logged in, you are automatically redirected to the login screen.
2. Data Initialization: The system automatically fetches the initial list of the 20 most recent ecommerce sales, along with the necessary data to populate filter dropdowns (such as available stores and user lists).
3. Filtering: You can refine the list using the filter bar, which includes options for Store, Document Number, Online Reference, Customer, Status, Delivery Method, Registration Number, and Date Ranges.
4. Search Execution: Once you have entered your desired criteria, clicking the "Search" button triggers a request to the system to update the table with the filtered results.
5. Viewing Details: The sales table displays key information for each order. You can click on specific items—such as the Document Number, Customer Name, or Registration Number—to navigate directly to the corresponding detail page for that record.

1.3 Key Concepts

- Ecommerce Sales List: A paginated table showing 20 sales at a time, sorted by the most recent creation date by default.
- Filter Bar: A set of search and selection tools that allow you to narrow down the list of sales based on specific business requirements.
- Status Badge: A visual indicator for each sale that shows its current progress (e.g., Draft, In Transit, or Completed).
- Deep Linking: The ability to click on specific data points (like a Document Number or Customer Name) to jump directly to a dedicated page for that entity.
- Session Security: An automated check that ensures only authorized users can access the sales data.

1.4 Business Value

This feature streamlines the management of online orders by providing a clear, searchable interface. By consolidating ecommerce sales data into a single view, staff can quickly identify the status of specific orders, resolve customer inquiries by navigating directly to customer or vehicle profiles, and maintain operational efficiency by filtering for specific fulfillment or store-related criteria.

2. Logic

2.1 Overview

The Ecommerce Sales dashboard provides a centralized view for tracking online sales transactions within the Lumi ERP system. When a user navigates to this page, the system automatically verifies their identity, retrieves the most recent ecommerce sales records, and populates the interface with relevant store and salesperson information to assist with order management.

2.2 Step-by-Step Flow

1. Authentication Check: Upon loading the page, the system verifies the user's active session. If the user is not logged in, they are automatically redirected to the login screen.
2. Data Retrieval: Once authenticated, the system simultaneously fetches three sets of data:

* A list of the 20 most recent ecommerce sales (excluding any voided transactions).

* A list of available stores.

* A list of registered users (salespeople).

3. Interface Population: The system processes the retrieved data to fill the main sales table and update the filter dropdowns for stores and salespeople, allowing the user to begin managing the data immediately.

2.3 Key Concepts

- Authentication: A security check that ensures only authorized users can access sales data.
- Ecommerce Sales: Transactions originating from online channels, filtered automatically to exclude voided or cancelled orders.
- Parallel Loading: A performance technique where the system fetches multiple pieces of information at the same time rather than waiting for each one to finish individually, resulting in a faster page load.
- Workflow State: A status indicator for each sale (e.g., completed, pending) that helps the system filter out irrelevant or voided records.

2.4 Business Value

-

Efficiency: By automating the retrieval of sales, store, and user data, the dashboard reduces manual effort and ensures the user is always looking at the most current information.

- Data Integrity: The system automatically filters out voided sales, ensuring that reporting and management tasks are based only on valid, active transactions.
- Security: The built-in session verification protects sensitive sales data by ensuring that only authenticated personnel can access the dashboard.

3. Data

3.1 Overview

The Ecommerce Sales feature provides a dedicated view within the Lumi ERP system to track and manage sales originating from your online channels. This feature pulls data from your online store and presents it in a clear, organized list, allowing your team to monitor order progress, customer details, and vehicle information in one centralized location.

3.2 Step-by-Step Flow

1. Data Retrieval: The system identifies all sales specifically marked with an "ecommerce" source.
2. Information Consolidation: The system gathers relevant details for each sale, including customer names, vehicle registration numbers, and the specific store location associated with the order.
3. Sorting: The list is automatically organized to show the most recently created sales at the top.
4. Formatting: The raw data is converted into a user-friendly format, ensuring that key information like order status, delivery method, and total amounts are clearly displayed.
5. Pagination: The system calculates the total number of ecommerce sales and presents them in manageable pages, allowing users to navigate through large volumes of orders efficiently.

3.3 Key Concepts

- Ecommerce Source: A filter that ensures only online-originated sales are displayed, keeping your digital sales data separate from in-store transactions.
- Workflow State: The current status of an order (e.g., pending, processing, or completed), which helps your team track where an order is in the fulfillment process.
- Reference Codes: The system tracks both your internal ERP document number and the original ecommerce reference number, making it easy to cross-reference orders with your online storefront.
- Pagination: A navigation tool that breaks down long lists of sales into smaller, readable pages to improve system performance and user experience.

3.4 Business Value

This feature streamlines operations by providing a single source of truth for all online sales. By integrating customer, vehicle, and store data into one view, your team can reduce the time spent switching between different platforms to verify order details. The structured list and pagination ensure that your staff can quickly locate specific orders, monitor fulfillment status, and maintain high levels of customer service for your online business.

BUSINESS REQUIREMENTS DOCUMENT

Sales List - Store /sales

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Store Sales list feature provides a centralized view for managing and monitoring retail sales transactions within the Lumi ERP system. This interface allows users to view a comprehensive list of sales, filter them by various criteria (such as store, customer, or status), and easily navigate to specific transaction details.

1.2 Step-by-Step Flow

1. Accessing the View: Users navigate to the Sales section and select the "Store" tab to view the list of retail sales.
2. Initial Data Loading: Upon loading, the system automatically fetches the most recent sales records (20 per page) and displays them in a table.
3. Filtering: Users can refine the list using the filter bar, which includes options for store, document number, customer, status, salesperson, and date ranges.
4. Applying Filters: Once the desired filters are set, the user clicks the "Search" button to update the table with the relevant results.
5. Reviewing Data: The table displays key transaction details, including document numbers, dates, customer names, vehicle registrations, status badges, and total amounts.
6. Navigation: Users can click on specific document numbers, customer names, or vehicle registration numbers to jump directly to the corresponding detail pages for more information.
7. Pagination: If there are more than 20 records, users can use the pagination controls at the bottom of the table to navigate through additional pages of sales data.

1.3 Key Concepts

- Filter Bar: A set of search and selection tools that allows users to narrow down the sales list based on specific business requirements.
- Status Badge: A visual indicator (e.g., "Draft" or "Completed") that helps users quickly identify the current stage of a sale.
- Pagination: A system that breaks large lists into manageable chunks of 20 records to ensure the page remains fast and easy to read.
- Drill-down Links: Interactive elements within the table that allow users to move from the summary list to detailed records for sales, customers, or vehicles.
-

Data Formatting: Standardized display rules for dates (dd-mmm-yyyy) and currency (Indonesian format) to ensure consistency across the platform.

1.4 Business Value

This feature streamlines the retail sales management process by providing a single, organized location to track transaction history. By offering robust filtering and quick navigation to detailed records, it reduces the time staff spend searching for information, improves accuracy in sales reporting, and allows for better oversight of store performance and individual transaction statuses.

2. Logic

2.1 Overview

The Sales List feature provides a centralized view for retail staff to monitor and manage store sales. It allows users to view a paginated list of transactions, filter results by specific stores or sales personnel, and navigate to detailed information for individual sales, customers, or vehicles.

2.2 Step-by-Step Flow

1. Authentication Check: When the page loads, the system verifies the user's session. If the user is not logged in, they are automatically redirected to the login screen.
2. Data Initialization: Once authenticated, the system simultaneously retrieves the initial list of sales (defaulting to the 20 most recent transactions), a list of all sales personnel, and a list of all stores.
3. Displaying Information: The retrieved sales data is mapped into a table, while the user and store lists populate the filter dropdowns.
4. Filtering: Users can narrow down the sales list by selecting a specific store or salesperson and clicking the "Search" button. The table updates to show only the relevant results.
5. Navigation: Users can move through the sales history using pagination controls, which load additional sets of 20 records as needed.
6. Drill-down: Users can click on specific items within the table (such as the document number, customer name, or vehicle registration) to view more detailed information about that specific sale, customer, or vehicle.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable pages (20 records at a time) to improve performance and readability.
- Filtering: The ability to refine the sales list based on specific criteria, such as the store location or the salesperson who handled the transaction.

- Session Validation: A security measure that ensures only authorized users can access the sales data.
- Data Mapping: The process of taking raw system information and organizing it into a user-friendly table format with clear labels like "Status," "Amount," and "Salesperson."

2.4 Business Value

This feature streamlines retail operations by providing a clear, searchable overview of sales activity. By enabling staff to quickly locate specific transactions and filter by store or employee, the system reduces administrative time spent searching for records. Furthermore, the ability to drill down into customer and vehicle details directly from the sales list ensures that staff have the necessary information at their fingertips to provide better customer service and maintain accurate sales records.

3. Data

3.1 Overview

The Sales List feature provides a centralized, organized view of all retail transactions within the Lumi ERP system. It allows staff to quickly browse, search, and navigate through sales records, ensuring that key transaction details—such as the customer involved, the vehicle sold, the store location, and the current status of the sale—are easily accessible in one place.

3.2 Step-by-Step Flow

1. Requesting Data: When a user opens the Sales List page, the system calculates which "page" of results to show based on the user's current view.
2. Retrieving Records: The system fetches a specific batch of sales records, sorted by the most recent transactions first.
3. Gathering Details: For every sale in that batch, the system automatically pulls in related information, including the customer's name, the vehicle's registration number, the store name, and the salesperson responsible.
4. Counting Totals: Simultaneously, the system counts the total number of sales in the database to ensure the pagination controls (e.g., "Page 1 of 10") are accurate.
5. Displaying the List: The compiled data is presented in a table format, where users can see the document number, status, total amount, and other key details for each transaction.

3.3 Key Concepts

- Pagination: A method of breaking a large list of sales into smaller, manageable pages to ensure the software remains fast and easy to navigate.
-

Workflow State: The current stage of a sale (e.g., pending, completed, or cancelled), which helps staff identify which transactions require immediate attention.

- Reference Code: A unique identifier for each sale that acts as a link, allowing users to click through to see the full transaction history.
- Linked Entities: Related information that is automatically connected to a sale, such as the specific customer, the vehicle involved, and the store where the transaction occurred.

3.4 Business Value

This feature improves operational efficiency by providing a clear, real-time overview of retail performance. By consolidating transaction data into a single, searchable list, staff can spend less time hunting for information and more time managing customer relationships. Furthermore, the inclusion of status tracking and direct links to customer and vehicle details allows for faster decision-making and better oversight of the entire sales lifecycle.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order List - Company /sales_orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Order List feature provides a centralized view for managing and tracking company sales orders. It displays a comprehensive table of orders, allowing users to quickly review key details such as customer information, delivery status, and associated documentation. The interface includes powerful filtering capabilities to help users locate specific orders efficiently and provides direct navigation to detailed order views.

1.2 Step-by-Step Flow

1. Initial Load: When the page opens, the system automatically retrieves the most recent sales orders (defaulting to the 20 newest entries) and displays them in the table.
2. Filtering: Users can narrow down the list by entering criteria into the filter bar—such as document numbers, purchase order numbers, date ranges, specific warehouses, customers, or sales statuses.
3. Search Execution: Upon clicking the "Search" button, the system applies only the active filters to the request, refreshing the table to show only the matching records.
4. Navigation: Users can click on any row in the table to be redirected to a dedicated detail page for that specific sales order.
5. Creation: A "New Sales Order" button is available to quickly initiate the process of creating a new order.

1.3 Key Concepts

- Filter Bar: A set of input fields that allows users to refine the list of orders based on specific business criteria, ensuring they only see relevant data.
- Sales Order Table: The primary display area that organizes order data into columns, including document identifiers, customer names, warehouse locations, and counts for related items like invoices and returns.
- Pagination: A system that manages large volumes of data by displaying a set number of records (20) at a time, ensuring the page remains fast and easy to navigate.
- Status Tracking: Visual indicators that show the current state of an order (e.g., whether it is closed or active) and provide insight into the progress of deliveries and invoices.

1.4 Business Value

This feature streamlines the sales management process by providing a "single source of truth" for all company sales orders. By enabling quick filtering and easy access to order details, it reduces the time staff spend searching for information. Furthermore, the inclusion of delivery, invoice, and return counts directly in the list view allows

for immediate operational oversight, helping teams stay informed on the fulfillment status of every order without needing to open each record individually.

2. Logic

2.1 Overview

The Sales Order List feature provides a centralized view for managing and tracking company sales orders. It allows users to quickly find specific orders using various search criteria and displays a clear, organized summary of order details, status, and related activity (such as deliveries and invoices) in a table format.

2.2 Step-by-Step Flow

1. Initial Load: When you first open the page, the system automatically retrieves the 20 most recent sales orders, sorted by their creation date.
2. Filtering: You can use the filter bar to narrow down the list. You can search by document number, purchase order number, date range, warehouse, customer, salesperson, or order status.
3. Data Retrieval: Once you click "Search," the system sends your specific criteria to the database, ignoring any empty fields to ensure the search is efficient.
4. Display: The system receives the matching orders and maps the raw data into a user-friendly table, showing key information like the order reference, customer name, status, and counts for related documents like invoices or returns.
5. Pagination: The system manages the list in manageable chunks, showing you the total number of available orders and allowing you to navigate through the results.

2.3 Key Concepts

- Filter Bar: A set of search fields that allows you to pinpoint specific sales orders based on business-relevant criteria.
- Sales Order Mapping: The process of translating raw system data into a readable table format, ensuring that fields like "Document Number" or "Customer" are clearly labeled for the user.
- Pagination: A method of organizing large amounts of data into smaller pages, which helps maintain system performance and makes the list easier to read.
- Sorting: The ability to organize the list by specific attributes (like date) to ensure the most relevant information appears first.

2.4 Business Value

This feature improves operational efficiency by providing sales and administrative teams with a "single source of truth" for all company sales orders. By offering robust filtering and a clear overview of order status and related documentation (deliveries/invoices), users can resolve customer inquiries faster, track order progress accurately, and reduce the time spent manually searching through records.

3. Data

3.1 Overview

The Sales Order List feature provides a centralized, searchable view of all company sales orders within the Lumi ERP system. It is designed to help users quickly locate specific orders by applying various search criteria, sorting the results, and navigating through large volumes of data efficiently.

3.2 Step-by-Step Flow

1. Initial Load: When you first open the Sales Order page, the system automatically displays the 20 most recent orders, sorted by their creation date.
2. Applying Filters: You can narrow down the list using the filter bar. You may search by document number, purchase order number, specific date ranges, warehouse location, customer, salesperson, or order status.
3. Processing Request: Once you click "Search," the system takes your selected criteria and retrieves only the matching records from the database.
4. Displaying Results: The system presents the filtered list, maintaining your preferred sorting and pagination settings so you can easily browse through the results.

3.3 Key Concepts

- Filtering: The ability to narrow down a large list of orders by entering specific details (like a customer name or order status) so you only see the information relevant to your current task.
- Pagination: A method of breaking a long list of records into smaller, manageable pages (e.g., 20 items at a time) to ensure the page loads quickly and remains easy to read.
- Sorting: The ability to organize the list based on specific columns, such as the date the order was created, to help you prioritize your work.
- Default View: The pre-configured state of the page that ensures you see the most relevant information (the newest orders) immediately upon arrival without needing to perform any manual searches.

3.4 Business Value

This feature significantly improves operational efficiency by reducing the time spent searching for order information. By providing robust filtering and organized views, staff can quickly respond to customer inquiries, track order statuses, and manage warehouse activities with greater accuracy and speed.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order Returns - List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Order Returns list page provides a centralized view for managing and tracking product returns within the Lumi ERP system. This page allows users to quickly search, filter, and review the status of all return requests, ensuring that the return process—from initial receipt to final approval—is transparent and easy to navigate.

1.2 Step-by-Step Flow

1. Accessing the Page: Users navigate to the Sales Order Returns section via the main navigation menu.
2. Filtering Data: Users can narrow down the list of returns using specific criteria, such as document number, date ranges, warehouse location, customer name, or current workflow status.
3. Reviewing the List: The system displays a table of returns, showing key details like the document number, associated invoices, dates, warehouse destination, customer, and current status.
4. Sorting and Navigation: Users can sort the list by most columns (excluding the Sales Order reference) to organize data as needed. The list is paginated in chunks of 20 records to ensure fast performance.
5. Taking Action:

– Users can click on a specific document number or row to view the full details of a return.

– Users can click the "New Sales Order Return" button to initiate a new return request.

1.3 Key Concepts

– Workflow States: The lifecycle of a return, which can be in one of four stages: Draft, Received, Approved, or Cancelled.

– Filter Bar: A set of controls that allows users to refine the list based on specific business parameters, such as date ranges or customer names.

– Pagination: A method of displaying data in manageable segments (20 items per page) to keep the interface clean and responsive.

– Sortable Columns: Most table columns allow users to reorder the list (e.g., by date or status) to help locate specific records faster.

– Linked Documents: Many fields in the table (such as Document Number or Sales Invoice) act as links, allowing users to jump directly to the relevant details page for that specific record.

1.4 Business Value

This feature streamlines the returns management process by providing a single, organized dashboard. By enabling quick filtering and sorting, staff can efficiently monitor the status of returns, identify bottlenecks in the approval workflow, and ensure that customer returns are processed accurately and in a timely manner.

2. Logic

2.1 Overview

The Sales Order Returns list feature provides a centralized view for tracking items returned by customers. This page allows users to quickly see the status of returns, identify which warehouse received them, and link back to the original sales orders or invoices. Upon opening the page, the system automatically verifies the user's access and displays the most recent returns without requiring manual search actions.

2.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the page, the system immediately checks if they are logged in. If the user is not authorized, they are automatically redirected to the login screen.
2. Automatic Data Load: Once authorized, the system automatically fetches the list of sales order returns using default settings, ensuring the table is populated as soon as the page loads.
3. Filtering: Users can narrow down the list using specific criteria such as the document number, date ranges, warehouse location, customer name, or the current workflow status.
4. Data Display: The system retrieves the relevant records and displays them in a clear table format, showing key details like the return status, dates, and associated sales documents.
5. Dynamic Updates: If a user applies filters, the system updates the table to show only the records that match those specific criteria.

2.3 Key Concepts

- Workflow State: The current stage of the return process (e.g., pending, received, or approved), helping users track progress.
- Reference Codes: Unique identifiers for the return document, the original sales order, and the sales invoice, allowing for easy cross-referencing.
- Filter-to-Query Mapping: The logic that ensures only active, non-empty search criteria are sent to the system, keeping the search results accurate and relevant.
- Inclusive Date Filtering: When searching by date, the system includes both the start and end dates provided to ensure no records are missed.

2.4 Business Value

- Improved Efficiency: By automatically loading the list upon page access, users save time and can immediately begin reviewing return activity.
- Enhanced Visibility: Providing a clear, filterable list of returns allows staff to quickly identify bottlenecks in the return process and respond to customer inquiries faster.
- Better Traceability: Linking returns directly to their original sales orders and invoices ensures that staff have all the necessary context to process returns accurately and maintain clean financial records.

3. Data

3.1 Overview

The Sales Order Returns list provides a centralized view for tracking all product returns within the Lumi ERP system. This feature allows staff to quickly see the status of returned items, identify which customer initiated the return, and track the progress of the return through the warehouse and approval process.

3.2 Step-by-Step Flow

1. Request: The system receives a request to view the returns list, defaulting to the most recent entries.
2. Data Retrieval: The system gathers return records, automatically pulling in related details such as the original sales order, the associated invoice, the customer name, and the destination warehouse.
3. Organization: The records are sorted by date, showing the newest returns at the top of the list.
4. Pagination: The system breaks the list into manageable pages (defaulting to 20 items per page) to ensure the interface remains fast and easy to navigate.
5. Display: The final list is presented to the user, showing key information like the return document number, current status, and the staff member who last updated the record.

3.3 Key Concepts

- Return Document Number: A unique reference code used to identify a specific return transaction.
- Workflow State: The current stage of the return process (e.g., pending, received, or approved).
- Linked References: The system automatically connects each return to its original Sales Order and Sales Invoice, allowing users to click through to those documents for more detail.
- Pagination: A method of displaying large amounts of data in smaller, separate pages to improve performance and readability.

3.4 Business Value

This feature improves operational efficiency by providing a "single source of truth" for all return activity. By consolidating information from sales, warehousing, and customer records into one view, staff can:

* Reduce Administrative Time: Eliminate the need to manually search through separate sales and warehouse logs to find return details.

* Improve Accountability: Easily identify the status of a return and see which user last updated the record.

* Enhance Customer Service: Quickly answer customer inquiries regarding the status of their return by referencing the real-time workflow state.

BUSINESS REQUIREMENTS DOCUMENT

Sales Deliveries List Page

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Deliveries List Page provides a centralized view for tracking all outgoing shipments. It allows users to search, filter, and organize delivery records, making it easy to monitor the status of orders as they move through the fulfillment process.

1.2 Step-by-Step Flow

1. Initial Load: When you open the page, the system automatically retrieves the full list of sales deliveries and populates the "Warehouse" dropdown menu with available options.
2. Filtering: You can narrow down the list by entering specific criteria, such as a delivery number, customer name, reference number, sales order, sales invoice, date range, warehouse location, or current status.
3. Search: Once you have entered your desired filters, clicking the "Search" button updates the table to display only the records that match your criteria.
4. Sorting: You can click on any column header (such as Date or Status) to reorder the list, helping you prioritize or find specific records more quickly.
5. Navigation: If you need to see more information about a specific shipment, you can click on any row in the table to open the detailed view for that delivery.
6. Pagination: If there are many deliveries, the system breaks the list into pages, allowing you to navigate through large volumes of data efficiently.

1.3 Key Concepts

- Filters: Tools that allow you to narrow down a large list of deliveries based on specific data points like dates, customers, or status.
- Warehouse Dropdown: A selection menu that ensures you only search for deliveries associated with valid, existing warehouse locations.
- Sortable Columns: A feature that lets you click table headers to organize data alphabetically or chronologically.
- Pagination: A method of splitting long lists into smaller, manageable pages to improve performance and readability.
- Row Selection: The ability to click on a specific delivery record to view its full, detailed information.

1.4 Business Value

- Improved Efficiency: Users can quickly locate specific shipments without manually scanning through long lists.

- Better Visibility: By linking deliveries to sales orders and invoices, the page provides a clear audit trail of the fulfillment process.
- Operational Control: The ability to filter by status and warehouse helps managers monitor bottlenecks and ensure that deliveries are being processed on time.
- Data Accuracy: Standardized search and filter options reduce the risk of human error when looking up order information.

2. Logic

2.1 Overview

The Sales Deliveries List page provides a centralized view for users to track and manage outgoing shipments. This page allows users to search for specific deliveries, filter results by various criteria (such as customer, warehouse, or status), and organize the data through sorting and pagination. It is designed to give staff quick access to delivery details, including associated sales orders, invoices, and current workflow statuses.

2.2 Step-by-Step Flow

1. Initial Load: When the page opens, the system automatically retrieves the full list of sales deliveries and populates the "Warehouse" filter dropdown menu with available options.
2. Filtering: Users can narrow down the list by entering specific criteria, such as a delivery number, reference number, customer, date range, or workflow status. The system updates the table to show only the records that match these selections.
3. Sorting: Users can click on any column header (e.g., Date, Status, or Customer) to reorder the list, making it easier to find the most relevant or urgent deliveries.
4. Pagination: To keep the page performance fast, the system displays deliveries in manageable chunks. Users can navigate through these chunks using page controls at the bottom of the table.
5. Data Display: The system maps the raw delivery information into a clear, readable table format, showing key details like the delivery number, associated sales order, invoice, customer name, and current status.

2.3 Key Concepts

- Filtering: The ability to narrow down a large list of deliveries based on specific attributes like date, customer, or warehouse.
- Pagination: A method of breaking a large list into smaller, numbered pages to improve loading speed and readability.
- Sorting: The ability to organize the table rows in ascending or descending order based on a selected column.

- Workflow State: The current stage of a delivery in the business process (e.g., pending, shipped, or delivered).
- Reference Number: A unique identifier used to cross-reference the delivery with external documents or internal records.

2.4 Business Value

This feature improves operational efficiency by allowing sales and warehouse teams to quickly locate and monitor the status of any delivery. By providing robust filtering and sorting capabilities, the page reduces the time spent searching for information, minimizes manual tracking errors, and ensures that staff have real-time visibility into the fulfillment process, ultimately leading to better customer service and faster issue resolution.

3. Data

3.1 Overview

The Sales Deliveries List page provides a centralized view of all outgoing shipments within the Lumi ERP system. This feature allows users to quickly monitor the status of deliveries, track which orders have been fulfilled, and see exactly where and to whom goods are being sent. By consolidating information from various parts of the system—such as warehouses, customers, and invoices—this page serves as a single source of truth for the logistics team.

3.2 Step-by-Step Flow

1. Data Retrieval: The system gathers all delivery records from the database, pulling in relevant details like the delivery number, date, and current status.
2. Information Consolidation: The system automatically links each delivery to its associated records, including the original sales order, the specific warehouse involved, the customer, and the corresponding invoice.
3. Sorting: The list is automatically organized to show the most recent deliveries at the top, ensuring users see the latest activity first.
4. Data Formatting: The system organizes this combined information into a clear, readable format that is ready to be displayed on the screen for the user.

3.3 Key Concepts

- Sales Delivery: A record representing the shipment of goods to a customer, including its unique tracking number and current progress.
- Workflow State: The current status of a delivery (e.g., pending, in transit, or completed), which helps users track progress.
-

Reference Number: An additional identifier used to cross-reference the delivery with external documents or internal tracking systems.

- Linked Records: The connection between a delivery and other business entities, such as the customer who ordered the items or the warehouse that fulfilled the request.

3.4 Business Value

This feature significantly improves operational efficiency by eliminating the need to manually search through separate order, invoice, and warehouse logs. By providing a unified list, staff can quickly answer customer inquiries regarding delivery status, identify bottlenecks in the shipping process, and maintain better oversight of the entire fulfillment lifecycle.

BUSINESS REQUIREMENTS DOCUMENT

Sales Service Reservation List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Service Reservation List feature provides a centralized dashboard for managing and tracking vehicle service appointments within the Lumi ERP system. It allows staff to quickly locate specific reservations using a variety of search criteria and provides a clear overview of the status of each appointment, from initial creation through to the final invoicing stage.

1.2 Step-by-Step Flow

1. Navigation: Upon entering the module, the system automatically highlights the "Sales" and "Service" tabs to ensure the user is in the correct workspace.
2. Filtering: Users can narrow down the list of reservations by entering criteria into the filter bar. Available filters include document numbers, date ranges, store locations, vehicle details (brand/model), customer contact information, and current reservation status.
3. Search: Once the desired filters are set, the user clicks the "Search" button to refresh the data table with the relevant records.
4. Review: The system displays a table containing all matching reservations, showing key details such as customer name, vehicle information, scheduled service times, and current status.
5. Action: Users can click on specific document numbers or vehicle registration numbers to view detailed information, or click the "New Service Reservation" button to initiate a new booking.

1.3 Key Concepts

- Service Reservation: A formal record of a customer's request for vehicle maintenance or repair.
- Filter Bar: A set of input fields and dropdowns that allow users to query the database for specific records based on business-relevant attributes.
- Status Badge: A visual indicator (e.g., "Draft" or "Confirmed") that helps staff immediately identify the progress of a reservation.
- Downstream Records: Linked documents such as Sales Orders, Work Orders, and Invoices that are generated as the reservation moves through the service lifecycle.

1.4 Business Value

- Operational Efficiency: By providing robust filtering, staff can instantly find specific customer or vehicle records without manually scanning long lists.
- Improved Visibility: The table view provides a "single source of truth" for the status of all service appointments, helping managers track the transition from a simple reservation to a completed invoice.
-

Seamless Workflow: The ability to jump directly from the list to a new reservation or an existing detail page reduces the number of clicks required to perform daily administrative tasks.

BUSINESS REQUIREMENTS DOCUMENT

Add Sales - Store /sales/new

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Add Sales" feature provides a streamlined interface for retail staff to process customer transactions. It allows users to build a sale by selecting a customer, assigning a salesperson, and choosing a register. The system supports adding multiple products and vouchers to a single transaction, automatically calculating totals, taxes, and payment balances to ensure accuracy at the point of sale.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically populates dropdown menus for Salespeople, Registers, and Payment Types by fetching the latest data.
2. Sale Header Setup: The user selects the required Customer (searchable by name, phone, birthdate, or ID), the Salesperson, and the Register. If a customer is not in the system, the user can quickly add them via a pop-up window. Optionally, a vehicle can be linked to the sale.
3. Adding Items: The user adds products to the sale. For each item, the system automatically fills in the price and discount information. The user only needs to input the quantity.
4. Adding Vouchers: If applicable, the user can switch to the Voucher tab to add vouchers to the transaction.
5. Billing & Summary: The system automatically calculates the subtotal, tax, and final total. If shipping is required, a dedicated form allows the user to add shipping costs to the final amount.
6. Payment: The user enters payment details. The system tracks the balance owed and calculates any change due.
7. Finalization: Once all details are confirmed, the user clicks "Save." The system validates that the required fields (Customer, Salesperson, and Register) are present before submitting the transaction.

1.3 Key Concepts

- Searchable Dropdowns: Fields that allow users to type a few characters to quickly find and select specific items, customers, or vouchers from the database.
- Auto-Calculation: A feature where the system performs math (like multiplying quantity by price or summing totals) in real-time, reducing manual entry errors.
- Required Fields: Essential information (Customer, Salesperson, Register) that must be provided before a sale can be finalized.
- Modal: A pop-up window that allows the user to perform a secondary task (like creating a new customer) without leaving the main sales screen.
-

Read-Only Fields: Information displayed on the screen that is automatically filled by the system and cannot be manually edited by the user.

1.4 Business Value

- Efficiency: By automating price lookups and total calculations, staff can process transactions faster, reducing wait times for customers.
- Data Accuracy: Centralizing the entry of sales, customer, and inventory data ensures that records are consistent and reliable for reporting.
- Flexibility: The ability to handle both standard product sales and voucher redemptions in one transaction simplifies the workflow for retail staff.
- Operational Control: Requiring specific fields like "Salesperson" and "Register" ensures that every transaction is properly attributed, which is critical for performance tracking and cash management.

2. Logic

2.1 Overview

The "Add Sales" feature provides a streamlined interface for retail staff to record transactions within the Lumi ERP system. It allows users to capture essential sale details—such as the customer, the salesperson, the register used, and the specific items sold—and save them directly to the system. The feature is designed to be intuitive, using searchable dropdowns to quickly find and link relevant information like customers, vehicles, and payment methods.

2.2 Step-by-Step Flow

1. Initialization: When the sales page loads, the system automatically retrieves and populates dropdown lists for Salespeople, Registers, and Payment Types so that staff can select the correct options immediately.
2. Data Entry: The user fills out the sale details. This includes searching for and selecting a customer, assigning a salesperson, choosing a register, and adding items to the sale. Optional information, such as vehicle details, promo codes, or sales notes, can also be added.
3. Validation: When the user clicks "Save," the system performs a mandatory check to ensure that a Customer, Salesperson, and Register have been selected. If any of these are missing, the system will prevent the sale from being saved.
4. Submission: Once validated, the system bundles all the entered information—including itemized products, discounts, taxes, and payment details—into a single record and sends it to the system database.
5.

Confirmation: Upon a successful save, the system confirms the transaction by generating a unique sale ID and timestamp.

2.3 Key Concepts

- Searchable Dropdowns: Interactive fields that allow users to type a few characters to quickly filter and select specific records (like customers or vehicles) from the database.
- Mandatory Fields: Essential information required to complete a transaction; the system will not allow a sale to be finalized without a Customer, Salesperson, and Register.
- Payment Mapping: The process of linking a specific payment method (e.g., cash, card, or voucher) to the amount paid, ensuring the financial record of the sale is accurate.
- Itemized Sales: The ability to list multiple products within a single transaction, with the system automatically calculating subtotals, discounts, and taxes for each line item.

2.4 Business Value

This feature centralizes retail sales operations, ensuring that every transaction is accurately recorded with the necessary accountability (who sold it and where). By automating the lookup of users, stores, and payment types, it reduces manual data entry errors and speeds up the checkout process. Furthermore, by capturing detailed information like vehicle associations and ecommerce references, the business gains better visibility into sales trends and customer history, supporting more informed decision-making.

3. Data

3.1 Overview

The "Add Sales" feature allows retail staff to record new transactions within the Lumi ERP system. This functionality captures the essential details of a sale—such as who made the purchase, which staff member processed it, and which cash register was used—ensuring that every transaction is accurately logged and linked to the specific items sold.

3.2 Step-by-Step Flow

1. Validation: The system checks that the essential information is provided, specifically the customer, the salesperson, and the cash register. If any of these are missing, the system will prevent the sale from being saved.
2. Transaction Initiation: Once the data is validated, the system begins a secure recording process to ensure all parts of the sale are saved together as a single unit.
3.

Recording the Sale Header: The system creates a primary record for the transaction, which includes the total amount and the exact time the sale occurred.

4. Recording Sale Items: The system then logs each individual product included in the transaction, linking them to the primary sale record created in the previous step.
5. Finalization: Once all items are successfully recorded, the system confirms the transaction is complete and provides a unique reference ID for the sale.

3.3 Key Concepts

- Sale Header: The main record of a transaction that captures the "who, where, and when" of the purchase.
- Sale Items: The individual line items within a transaction, detailing which specific products were bought, in what quantity, and at what price.
- Transactional Integrity: A safety mechanism that ensures that if any part of the sale fails to save, the entire transaction is rolled back to prevent incomplete or corrupted data.
- Validation: A mandatory check performed by the system to ensure that critical information is present before allowing the record to be created.

3.4 Business Value

This feature provides a reliable foundation for retail operations by ensuring that all store sales are captured consistently. By linking sales to specific staff members and registers, the business gains better visibility into store performance and accountability. Furthermore, the structured data collection allows for accurate reporting and tracking of product movement, which is essential for maintaining healthy inventory levels and understanding customer purchasing habits.

BUSINESS REQUIREMENTS DOCUMENT

Sales Details - Store

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Details page provides a comprehensive view of an individual retail transaction within the Lumi ERP system. It allows staff to review transaction data, monitor the current workflow status, and perform necessary actions such as finalizing or canceling a sale. The page is designed to be dynamic, showing relevant information based on the sale's current state.

1.2 Step-by-Step Flow

1. Loading Data: When you open a specific sales record, the system automatically retrieves all relevant transaction details, including customer information, product line items, payment summaries, and timestamps.
2. Viewing Details: The page displays a structured summary of the sale, including the reference code, store location, salesperson, and specific product details.
3. Monitoring Status: A status bar at the top indicates whether the sale is currently a "Draft" or "Completed."
4. Taking Action:

* If the sale is in "Draft" status, you have the option to "Complete" the sale or "Cancel" it.

* If you choose to change the status, a confirmation window will appear to prevent accidental updates.

* You can also use the "Print and Send" button at any time to generate a PDF of the transaction for email distribution.

1.3 Key Concepts

- Draft Status: The initial state of a sale after it has been created but before it is finalized.
- Completed Status: The final state of a sale, indicating the transaction has been fully processed and executed.
- Workflow Status Bar: A visual indicator that shows the current progress of the sale and provides access to status-changing actions.
- Confirmation Modal: A safety pop-up that requires you to verify your intent before the system permanently updates the status of a sale.
- Line Items Table: A detailed breakdown of the products included in the sale, showing quantities, pricing, and any applied discounts.

1.4 Business Value

- Operational Efficiency: By centralizing all transaction data and status controls in one view, staff can quickly manage sales without navigating between multiple screens.
-

Data Integrity: The use of confirmation modals for status changes reduces the risk of human error, ensuring that sales are only finalized or canceled intentionally.

- Improved Customer Service: The ability to instantly print or email transaction details allows for faster communication with customers regarding their purchases.
- Transparency: Clear tracking of timestamps (created, updated, and completed) and user attribution provides a reliable audit trail for every transaction.

2. Logic

2.1 Overview

The Sales Details feature provides a centralized view for managing individual retail transactions within the Lumi ERP system. It allows staff to view comprehensive transaction data—such as store location, total amounts, and current status—and manage the lifecycle of a sale from its initial draft phase through to completion.

2.2 Step-by-Step Flow

1. Data Retrieval: When a user opens a sales record, the system automatically fetches the transaction details, including the specific store location and financial totals.
2. Information Display: The system maps internal database records to the screen, ensuring fields like the reference code, date, customer information, and salesperson are clearly visible to the user.
3. Payment Summary: The system calculates the final total (including tax) and determines the change due by comparing the total amount against the payments provided by the customer.
4. Status Management: Users can monitor the sale via the Workflow Status Bar. If a change is requested (e.g., moving from "Draft" to "Completed"), the system prompts for confirmation.
5. Validation: Before finalizing a status change, the system verifies that the sale is not already marked as "Completed." If the sale is already finished, the system prevents further modifications to ensure data integrity.

2.3 Key Concepts

- Sales Transaction: The core record containing all details of a retail sale, including financial data, store context, and current progress.
- Workflow Status: A tracking mechanism that identifies whether a sale is currently a "Draft" (in progress) or "Completed" (finalized).
- Payment Summary: An automated calculation that ensures the amount paid by the customer matches the transaction total and accurately reflects any change owed.
- Data Mapping: The process of translating raw system data into a user-friendly format displayed on the screen.

2.4 Business Value

- Operational Efficiency: By automating the calculation of totals and change, the system reduces manual errors and speeds up the checkout process.
- Data Integrity: The built-in validation prevents accidental changes to finalized sales, ensuring that financial records remain accurate and reliable.
- Improved Visibility: Providing a clear, mapped view of transaction details allows staff to quickly access necessary information about customers, products, and store performance, leading to better customer service.

3. Data

3.1 Overview

The "Sales Details - Store" feature provides a centralized view for monitoring the performance of individual retail locations within the Lumi ERP system. It allows users to pull specific sales records for a chosen store over a defined timeframe, while also providing high-level performance metrics to help managers quickly assess how a specific location is performing.

3.2 Step-by-Step Flow

1. Identify the Store: The system retrieves the specific profile and metadata for the selected store to ensure the user is viewing the correct location.
2. Define the Timeframe: The user selects a start and end date to narrow down the sales activity they wish to review.
3. Retrieve Transaction Records: The system gathers all individual sales transactions that occurred at that specific store within the chosen date range.
4. Calculate Performance Metrics: The system automatically aggregates the data to provide a summary, including the total revenue generated and the total number of transactions processed for that store.

3.3 Key Concepts

- Store Metadata: The descriptive information about a store, such as its name, location code, and region, which provides context for the sales data.
- Sales Transactions: Individual records of sales events, including the date, the total amount paid, and the current status of the sale.
- Aggregated Metrics: A summary calculation that combines individual transaction data into meaningful totals, such as total revenue and transaction volume, to give a quick snapshot of store health.

3.4 Business Value

This feature empowers store managers and regional leads to make data-driven decisions by providing clear visibility into store performance. By combining detailed transaction logs with summarized revenue metrics, users can easily identify sales trends, track daily performance, and compare results across different time periods without needing to manually calculate totals.

BUSINESS REQUIREMENTS DOCUMENT

Add Sales Order - Company /sales_orders/new

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Sales Order" feature provides a streamlined interface for creating new sales orders within the Lumi ERP system. It allows users to select a warehouse, identify a customer, and build a list of products to be sold. The system includes flexible pricing and discount tools, ensuring that sales staff can accurately record order details before submitting them for processing.

1.2 Step-by-Step Flow

1. Initialization: Upon opening the page, the system automatically retrieves and displays a list of available warehouses.
2. Order Header Setup: The user selects the source warehouse and the customer. The system automatically populates the delivery address based on the selected customer.
3. Adding Items: The user adds products to the order. For each product, the system displays available stock levels to help guide the order quantity.
4. Pricing and Discounts:

* Users can enter a simple percentage discount directly in the product row.

* For more complex needs (such as fixed-amount discounts or tax-inclusive adjustments), users can open a dedicated "Discount Popup" for that specific item.

* A global "Set" tool is available to apply a uniform percentage discount to all items in the order at once.

5. Review and Save: The system calculates totals automatically. Once the required fields (Warehouse, Customer, and at least one product) are filled, the user clicks "Save" to submit the order as a draft.

1.3 Key Concepts

- Warehouse Selection: A mandatory step that defines where the stock for the order will be sourced.
- Customer Search: A type-ahead search feature that retrieves customer details and automatically fills in the delivery address.
- Discount Types: The system supports two ways to reduce prices: a percentage-based discount or a fixed-amount deduction.
- Tax-Inclusive Toggle: A setting that determines whether a discount is applied to the gross price (including tax) or the net price (before tax).
- Draft State: All new orders are initially saved as "Drafts," allowing for review or approval before they are finalized and delivered.

1.4 Business Value

This feature centralizes the sales order process, reducing manual data entry errors by pre-filling customer information and automating price calculations. By providing both quick-entry discount shortcuts and advanced configuration options, the system balances efficiency for standard sales with the flexibility required for complex pricing agreements. This ensures that the sales team can generate accurate, professional orders quickly, keeping inventory and financial records in sync from the moment an order is created.

2. Logic

2.1 Overview

The "Add Sales Order" feature allows users to create new sales orders within the Lumi ERP system. This interface provides a structured way to capture customer details, shipping information, and specific product line items, including any applicable discounts. Once the user completes the form and clicks "Save," the system validates the information and securely transmits it to the server to generate a new draft sales order.

2.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves a list of available warehouses to populate the "From Warehouse" selection menu.
2. Data Entry: The user fills out the order header (Customer, Warehouse, Delivery Date, etc.) and adds one or more product rows.
3. Search Assistance: As the user types in the "Customer" or "Product" fields, the system provides real-time search suggestions to ensure accurate selection.
4. Discount Management: Users can apply discounts to individual items using either a quick percentage shortcut or a detailed editor for specific discount amounts and tax settings.
5. Validation: Upon clicking "Save," the system checks that a customer and warehouse are selected and that at least one product with a valid quantity has been added.
6. Submission: If valid, the system packages the form data—including combining the address and zip code—and sends it to the server.
7. Confirmation: The server processes the request, generates a unique document number, calculates final totals, and returns a confirmation that the draft order has been created.

2.3 Key Concepts

– Type-ahead Search: A feature that suggests matching customers or products as you type, reducing manual entry errors.

- Draft State: The initial status of a new sales order, allowing for review before it is finalized or processed.
- Validation Rules: Built-in safeguards that prevent an order from being saved if essential information (like the customer or product quantity) is missing.
- Payload Mapping: The behind-the-scenes process where the information you enter into the form is organized into the specific format required by the system's database.

2.4 Business Value

- Data Accuracy: By using searchable dropdowns and mandatory field checks, the system ensures that sales orders are created with complete and correct information.
- Efficiency: Automating the calculation of totals and the generation of document numbers on the server side saves time and reduces the risk of manual calculation errors.
- Flexibility: The discount editor allows sales staff to apply various pricing strategies (percentage-based or fixed-amount) directly at the line-item level, providing better control over sales margins.

3. Data

3.1 Overview

The "Add Sales Order" feature allows users to create a new sales record within the Lumi ERP system. This process captures essential customer information, delivery details, and a list of products being ordered. The system automatically handles the administrative side of the order—such as generating a unique tracking number and reserving stock—to ensure that the order is accurate and ready for fulfillment from the moment it is saved.

3.2 Step-by-Step Flow

1. Submission: The user submits the sales order form, which includes customer details, delivery information, and a list of items with their respective pricing and discount settings.
2. Validation: The system checks that all mandatory information (such as the customer and the list of items) is present.
3. Document Numbering: The system automatically generates a unique document number for the order to ensure it can be easily tracked and referenced.
4. Record Creation: The system saves the main order details (the "header") and links all individual product items to that specific order.
5. Inventory Reservation: The system automatically triggers a stock reservation process to ensure the items ordered are set aside for this specific customer.
6.

Confirmation: Once all steps are successfully completed, the system confirms the order has been created and provides the full details of the saved record. If any part of this process fails, the system cancels the entire action to prevent incomplete or corrupted data.

3.3 Key Concepts

- Sales Order Header: The top-level information for an order, including the customer, delivery address, due date, and notes.
- Sales Order Items: The individual products included in the order, along with their specific quantities, prices, and any applied discounts.
- Atomic Transaction: A safety mechanism that ensures all parts of the order (header and items) are saved together; if one part fails, nothing is saved, preventing "half-finished" orders.
- Stock Reservation: An automated check that ensures the products requested are accounted for in the warehouse inventory as soon as the order is placed.

3.4 Business Value

- Data Integrity: By using automated document numbering and atomic transactions, the system prevents duplicate records and ensures that orders are never saved with missing or mismatched information.
- Operational Efficiency: Automating the stock reservation process removes the need for manual inventory checks, allowing sales staff to confirm availability immediately.
- Accuracy: By recalculating financial fields and validating data upon submission, the system reduces human error in pricing and discount calculations, ensuring that the final order reflects the correct totals.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order Details

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Order Details page provides a comprehensive view of a specific sales order within the Lumi ERP system. It acts as a central hub for users to review order information, track the progress of an order through its lifecycle, and perform necessary administrative actions like approving or delivering the order.

1.2 Step-by-Step Flow

1. Authentication & Loading: When you open the page, the system verifies your login status. If you are not logged in, you will be redirected to the login screen.
2. Data Retrieval: The system fetches the specific details for the requested order ID.
3. Information Display: The page populates with the order's header information (such as document numbers, customer details, and dates), a list of items included in the order, and the financial totals.
4. Workflow Tracking: A status bar at the top highlights the current stage of the order: Draft, Approved, or Delivered.
5. Action Execution: Depending on the current status of the order, you can perform specific actions:

* Print: Available at any time to generate a proforma invoice.

* Approve: Available if the order is in "Draft" status.

* Deliver: Available if the order is in "Approved" status.

* Cancel: Available if the order is in "Draft" or "Approved" status.

1.3 Key Concepts

- Workflow Status: A visual indicator showing the current stage of the order (Draft, Approved, or Delivered).
- Header Information: Key metadata about the order, including reference codes, warehouse origin, customer destination, and timestamps for creation and updates.
- Order Items Table: A detailed breakdown of the products ordered, including SKU, quantity, pricing, discounts, and the final amount per line item.
- Financial Summary: The calculation of the order's subtotal, tax, and final total amount.
- Action Buttons: Context-aware controls that allow users to move the order forward in the workflow or print documentation.

1.4 Business Value

This feature centralizes all critical information regarding a sales order, reducing the need to navigate between different screens to find data. By providing clear status tracking and role-appropriate action buttons, it ensures that the sales process remains organized, transparent, and efficient, helping teams manage order fulfillment from initial entry to final delivery with minimal errors.

2. Logic

2.1 Overview

The Sales Order Details page provides a comprehensive view of a specific customer order within the Lumi ERP system. It acts as a central hub for users to review order information, including customer details, items purchased, financial totals, and the current progress of the order. The page is designed to be dynamic, adjusting the available action buttons based on the order's current status to ensure users only perform relevant tasks.

2.2 Step-by-Step Flow

1. Security Verification: When a user navigates to the page, the system automatically checks their login session. If the user is not logged in, they are redirected to the login screen.
2. Data Retrieval: The system identifies the specific order from the web address and fetches all relevant details, such as customer information, warehouse location, item lists, and pricing.
3. Information Display: The retrieved data is organized into three clear sections:

* Header: Contains administrative details like document numbers, dates, notes, and the assigned salesperson.

* Items Table: Lists every product in the order, including quantities ordered versus delivered, pricing, and discounts.

* Totals: Displays the subtotal, tax, and final order amount.

4. Status-Based Actions: The system checks the order's status (Draft, Approved, or Delivered) to display the appropriate action buttons:

* Draft: Allows the user to "Approve" the order.

* Approved/Delivered: Allows the user to generate a "Proforma Invoice."

* All Statuses: Always provides a "Print" option.

2.3 Key Concepts

– Workflow Status: A visual indicator that tracks the lifecycle of an order (Draft, Approved, or Delivered), which dictates what actions a user can take.

– Header Information: The top section of the page containing metadata, such as who created the order, when it was updated, and the associated customer or warehouse.

–

Order Items Table: A detailed breakdown of the products, showing the relationship between what was requested (Order Qty) and what has been fulfilled (Delivered Qty).

- Action Buttons: Context-sensitive controls that appear based on the order status to prevent errors and streamline the workflow.

2.4 Business Value

This feature improves operational efficiency by providing a single, reliable source of truth for sales orders. By tailoring the interface to the order's status, the system reduces user error and guides staff through the correct business process—ensuring that, for example, a draft order cannot be invoiced before it is approved. This clarity helps sales and warehouse teams coordinate effectively and maintain accurate records.

3. Data

3.1 Overview

The Sales Order Details page provides a comprehensive view of a specific sales order within the Lumi ERP system. It acts as a central hub where users can review all critical information related to a transaction, including customer details, shipping information, the list of products ordered, and the final financial breakdown.

3.2 Step-by-Step Flow

1. Request: The system receives a request to view a specific sales order by its unique identifier.
2. Data Retrieval: The system gathers the primary order information, including the status, dates, and financial totals.
3. Information Enrichment: The system pulls in related details to provide a complete picture, specifically linking the order to the correct customer and warehouse records.
4. Line Item Compilation: The system retrieves all individual products associated with that order, including quantities, pricing, and any applied discounts.
5. Display: All gathered information is organized and presented on the page, grouping data into the order header, the itemized product list, and the final financial summary.

3.3 Key Concepts

- Sales Order Aggregate: A complete collection of all data related to a single order, ensuring that the user sees a unified view rather than fragmented pieces of information.
- Line Items: The individual products or services included in an order, detailing what was ordered versus what has been delivered.

- Financial Summary: The breakdown of the order costs, including the subtotal, tax, and the final total amount.
- Workflow Status: A visual indicator (such as Draft, Approved, or Delivered) that helps users quickly understand the current stage of the order in the business process.

3.4 Business Value

This feature improves operational efficiency by providing sales and warehouse teams with a "single source of truth" for any given order. By consolidating customer, warehouse, and product data into one view, staff can quickly verify order accuracy, track delivery progress, and resolve customer inquiries without needing to navigate between multiple screens or systems.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order Return New /sales_order_returns/new

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Sales Order Return" feature allows staff to process product returns from customers. This interface ensures that returns are linked to valid, existing sales invoices, maintains accurate inventory tracking by requiring a destination warehouse, and prevents over-returning items by validating quantities against the original invoice.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system prepares the form by loading available warehouses and customers. The return number is left blank, as it is generated automatically upon saving.
2. Customer Selection: The user selects a customer. This action clears any previously selected invoices or products to ensure data consistency.
3. Invoice Selection: Once a customer is chosen, the system displays a list of their eligible sales invoices. Selecting an invoice automatically populates the product table with items from that specific order.
4. Return Details: For each product, the user enters the quantity to be returned and a reason for the return. The system automatically calculates the total quantity and total monetary value of the return.
5. Validation: The system ensures that the returned quantity for any item does not exceed the "remaining" quantity (the amount not yet returned from the original invoice).
6. Submission: Once the user clicks "Save," the system validates that a warehouse, customer, and invoice are selected, and that at least one item is being returned.
7. Completion: Upon a successful save, the system generates a new return record and automatically navigates the user to the details page for that specific return.

1.3 Key Concepts

- Remaining Quantity: A system-calculated limit that prevents users from returning more items than were originally purchased or previously returned.
- Draft Status: The initial state of a new return record, indicating it has been created but not yet processed or approved.
- Invoice-Linked Returns: A safety mechanism where returns must be tied to a specific, valid sales invoice to ensure accurate financial and inventory records.
- Total Returned/Amount: Real-time calculations that update as the user modifies quantities, providing immediate visibility into the scope of the return.

1.4 Business Value

- Data Integrity: By linking returns directly to invoices and enforcing quantity limits, the system prevents errors and unauthorized returns.
- Operational Efficiency: Automating the calculation of return totals and streamlining the selection process reduces manual data entry and potential for human error.
- Inventory Accuracy: Requiring a destination warehouse ensures that returned goods are tracked correctly within the company's inventory system from the moment the return is initiated.

2. Logic

2.1 Overview

The "Sales Order Return" feature allows users to initiate a return process for items previously sold to a customer. By selecting a customer and a specific invoice, the system automatically identifies which products are eligible for return. The feature ensures data integrity by validating quantities against remaining stock before creating a formal return record in the system.

2.2 Step-by-Step Flow

1. Customer Selection: The user selects a customer from the dropdown. The system automatically clears any previously selected invoices or product data to ensure the new return is accurate.
2. Invoice Loading: Once a customer is selected, the system fetches and displays a list of all invoices eligible for return for that specific customer.
3. Product Review: After an invoice is selected, the system displays the items from that invoice. Each item shows a "Remaining" quantity, which indicates how many units are still eligible for return (accounting for any previous returns).
4. Form Completion: The user enters the quantity to be returned and a reason for each item. The system prevents the user from entering a quantity higher than the "Remaining" amount.
5. Submission: Upon clicking "Save," the system validates the form one final time. If valid, it creates the return record.
6. Navigation: Once successfully saved, the system automatically redirects the user to the "Sales Order Return Details" page, where the return is set to "Draft" status, allowing for further processing or cancellation.

2.3 Key Concepts

- Remaining Quantity: A read-only value that tracks how many units of an item are still eligible for return. It automatically subtracts any quantities already returned in previous transactions.
-

Draft Status: The initial state of a newly created return, where the record is saved but not yet finalized, allowing for final review or adjustments.

- Validation: A built-in safety check that ensures all required fields (Warehouse, Customer, Invoice) are filled and that return quantities do not exceed the available balance.
- Eligible Invoices: Only invoices that have items available for return are displayed, simplifying the selection process for the user.

2.4 Business Value

- Accuracy: By automatically calculating the "Remaining" quantity, the system prevents over-returning of items, reducing manual errors and inventory discrepancies.
- Efficiency: The automated flow from customer selection to invoice filtering saves time by removing the need for users to manually search for or verify returnable items.
- Auditability: Every return is linked to a specific invoice and customer, ensuring a clear trail of documentation for all returned goods.
- Workflow Control: By moving the user to a "Draft" state upon creation, the system enforces a structured process, ensuring that returns are properly reviewed before they are finalized.

3. Data

3.1 Overview

The "New Sales Order Return" feature allows staff to initiate the process of returning items from a previously issued sales invoice. This feature captures the necessary details—such as which items are being returned, the quantity, the reason for the return, and the destination warehouse—to ensure accurate inventory and financial tracking within the Lumi ERP system.

3.2 Step-by-Step Flow

1. Form Entry: The user fills out the return form, selecting the customer, the original sales invoice, and the warehouse where the items will be returned.
2. Item Selection: The user specifies the quantity to be returned for each item from the invoice and provides a reason for each return.
3. Validation: Upon clicking "Save," the system checks that at least one item has a return quantity greater than zero. If no items are selected, the system prevents submission and displays an error.
4. Submission: The system processes the request, ensuring that only items with a valid return quantity are included. To prevent errors, the "Save" button is disabled during this process to avoid duplicate submissions.

5. Confirmation and Navigation: Once successfully created, the system automatically redirects the user from the entry form to the specific "Sales Order Return Details" page for the new record, where the return status is set to "Draft."

3.3 Key Concepts

- Sales Order Return: A formal record documenting that goods previously sold to a customer are being brought back into inventory.
- Sales Invoice: The original document representing the sale, which serves as the reference point for identifying which items are eligible for return.
- Draft Status: The initial state of a new return record, indicating that the return has been created but has not yet been finalized or processed into the warehouse.
- Validation: A safety check performed by the system to ensure that the data entered is complete and logical before it is saved to the database.

3.4 Business Value

This feature streamlines the returns process by centralizing data entry and ensuring that every return is linked to an original invoice. By requiring specific reasons for returns and validating quantities before submission, the system reduces manual errors, improves inventory accuracy, and provides a clear audit trail for customer service and accounting teams.

BUSINESS REQUIREMENTS DOCUMENT

Sales Deliveries Details Page /sales_deliveries/[record_id]

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Deliveries Details page provides a comprehensive view of a specific delivery record within the Lumi ERP system. It allows users to review all relevant information regarding a delivery—such as customer details, warehouse origin, itemized product lists, and financial summaries—and manage the delivery lifecycle through status updates and barcode printing.

1.2 Step-by-Step Flow

1. Authentication & Loading: When you navigate to a delivery page, the system verifies your login status. If you are not logged in, you will be redirected to the login screen.
2. Data Retrieval: The system fetches the specific details for the delivery record identified in the web address.
3. Information Display: The page organizes the data into three clear sections:

* Header: Displays key metadata, including document numbers, customer and warehouse information, dates, and the current workflow status.
* Items Table: Lists all products included in the delivery, showing quantities, pricing, discounts, and subtotals.
* Footer: Provides the final financial summary, including the subtotal, tax, and the grand total.

4. Workflow Management: Using the action bar, you can perform specific tasks:

* Deliver: Confirms the delivery status (requires a final confirmation).
* Cancel: Voids the delivery record (requires a final confirmation).
* Print Barcodes: Opens a dedicated tool to configure and print barcodes for the items in the delivery.

1.3 Key Concepts

- Workflow State: The current stage of the delivery process (e.g., Draft or Delivered), which determines which actions are available to the user.
- Confirmation Modal: A pop-up window that appears before critical actions (like confirming or cancelling a delivery) to prevent accidental changes.
- Barcode Configuration: A specialized interface that allows you to select a print template and specify the number of copies needed before generating a preview or printing.
- Line Items: The individual products or services associated with a specific delivery, detailed with their respective quantities and costs.

1.4 Business Value

This feature centralizes all critical delivery information into a single, easy-to-read interface, reducing the time spent searching for order details. By providing clear, guided workflows for confirming deliveries and cancelling errors, the system minimizes manual data entry mistakes and ensures that inventory and sales records remain accurate and up-to-date. Additionally, the integrated barcode printing capability streamlines warehouse operations, ensuring that items are correctly labeled and ready for shipment.

2. Logic

2.1 Overview

The Sales Delivery Details page provides a comprehensive view of a specific delivery record within the Lumi ERP system. It allows authorized users to review all relevant information regarding a delivery, including customer details, warehouse origin, itemized lists of products, and financial totals. The page also features a dynamic status bar that guides users through the delivery workflow by offering relevant actions based on the current state of the document.

2.2 Step-by-Step Flow

1. Authentication: When a user navigates to the page, the system verifies their identity. If the user is not logged in, they are automatically redirected to the login screen.
2. Data Retrieval: Once authenticated, the system fetches the specific delivery details using the unique record ID found in the web address.
3. Information Display: The system populates the page with the retrieved data, organizing it into three main areas:

* Header Information: Displays key references such as the document number, purchase order number, associated sales orders/invoices, warehouse and customer contact details, and audit timestamps.

* Delivery Items Table: Lists every product included in the delivery, showing quantities, pricing, discounts, and line-item totals.

* Financial Summary: Displays the final subtotal, tax, and grand total for the delivery.

4. Workflow Management: The system checks the current status of the delivery to determine which actions are available:

* If the status is "Draft," the user is presented with options to "Deliver" or "Cancel."

* If the status is "Delivered," the user is presented with the option to "Create Invoice."

2.3 Key Concepts

–

Workflow State: The current phase of the delivery process (e.g., Draft or Delivered), which dictates what actions a user can perform next.

- Sales Delivery Record: The central document containing all data related to a specific shipment of goods to a customer.
- Line Items: The individual products or services included in a delivery, detailed with their specific quantities and pricing.
- Audit Trail: Information displayed on the page (such as "Created By" and "Updated At") that provides transparency regarding who managed the record and when changes were made.

2.4 Business Value

This feature centralizes all critical delivery information into a single, easy-to-read interface, reducing the time staff spend searching for data across different documents. By automating the workflow actions based on the delivery status, the system prevents manual errors and ensures that users only perform valid operations (such as creating an invoice only after a delivery is finalized), thereby streamlining the sales-to-fulfillment process.

3. Data

3.1 Overview

The Sales Delivery Details page provides a comprehensive view of a specific delivery record within the Lumi ERP system. This page acts as a central hub, pulling together all relevant information—such as customer details, warehouse origin, associated sales orders, and financial totals—into a single, easy-to-read interface. It allows users to verify the status of a delivery and review the specific items included in the shipment.

3.2 Step-by-Step Flow

1. Record Retrieval: When you select a specific delivery, the system gathers all primary information for that record, including the delivery date, workflow status, and internal notes.
2. Contextual Linking: The system automatically pulls in related data from other areas of the ERP, such as the original Sales Order, the corresponding Sales Invoice, the Warehouse location, and the Customer profile.
3. Itemization: The system retrieves the list of all products included in the delivery, displaying details like the SKU, product name, quantity delivered, and individual pricing.
4. Financial Calculation: The system aggregates the line items to display the final financial summary, including the subtotal, tax, and the final total amount for the delivery.
5. Display: All gathered information is presented on the screen, organized into a header (for general delivery info), a table (for the list of items), and a footer (for financial totals).

3.3 Key Concepts

- Workflow State: The current stage of the delivery process (e.g., Draft or Delivered), which helps users understand where the document sits in the business lifecycle.
- Line Items: The individual products associated with a delivery, including their specific quantities and pricing details.
- Associated Records: Links to other documents or entities (like Sales Orders or Invoices) that provide the necessary context for why and how this delivery was created.
- Financial Summary: The breakdown of costs, including taxes and discounts, providing a clear view of the delivery's monetary value.

3.4 Business Value

- Improved Visibility: By consolidating data from multiple sources (Warehouse, Sales, Finance) into one view, users no longer need to navigate between different screens to verify delivery details.
- Operational Efficiency: Staff can quickly confirm delivery accuracy, check customer purchase order numbers, and review warehouse information, reducing the time spent on administrative verification.
- Audit Readiness: With clear tracking of who created or updated the record and when it was delivered, the system provides a reliable trail for internal reporting and accountability.

BUSINESS REQUIREMENTS DOCUMENT

New Sales Service Reservation

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The New Sales Service Reservation feature provides a streamlined interface for staff to schedule vehicle service appointments within the Lumi ERP system. This form ensures that all critical information—such as the customer, vehicle, and service timing—is captured accurately before a reservation is finalized. The system also includes flexible options to add multiple service items and record additional administrative details.

1.2 Step-by-Step Flow

1. Document Initialization: The system displays an auto-generated document number, which serves as the unique identifier for the reservation once saved.
2. Core Selection: The user selects the servicing store, the customer, and the specific vehicle from existing records. If a customer is not yet in the system, the user can trigger a quick action to add them.
3. Scheduling: The user enters the planned date and time for the service drop-off.
4. Vehicle Status: The user inputs the current odometer reading to ensure accurate vehicle history tracking.
5. Service Details: The user lists the specific services required. The system allows for multiple service items to be added dynamically as needed.
6. Optional Information: The user may optionally assign a service advisor or salesperson, note the booking source, and include any additional comments or instructions.
7. Validation and Submission: Upon clicking save, the system verifies that all required fields are completed. If valid, the reservation is submitted to the system.

1.3 Key Concepts

- Required Fields: Essential data points (such as store, customer, vehicle, date, time, and odometer) that must be provided to successfully create a reservation.
- Dynamic Item List: A flexible table structure that allows users to add as many individual service descriptions as necessary for a single appointment.
- Auto-generated Document Number: A system-assigned reference code that ensures every reservation is uniquely tracked without manual input.
- Immediate Validation: A built-in check that provides instant feedback if a user misses a required field, preventing incomplete data from being saved.

1.4 Business Value

- Data Integrity: By enforcing mandatory fields and validation, the system ensures that every reservation contains the necessary information for service teams to prepare effectively.
-

Operational Efficiency: The ability to add new customers on the fly and dynamically add multiple service items reduces administrative friction during the booking process.

- Improved Tracking: Capturing odometer readings and specific service descriptions at the point of booking creates a reliable audit trail for vehicle maintenance history, which is critical for long-term customer service and vehicle resale value.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order Detals - Quotation/Deliveries/Invoices/Returns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Sales Order Related Documents" page provides a centralized view of all activity associated with a specific sales order. Instead of searching through different parts of the system, users can view a comprehensive history of quotations, deliveries, invoices, and returns linked to a single order on one screen. This page acts as a hub for tracking the lifecycle of a sale from the initial quote to final fulfillment or potential returns.

1.2 Step-by-Step Flow

1. Authentication Check: When you open the page, the system verifies your login session. If you are not logged in, you are automatically redirected to the login screen.
2. Data Retrieval: The system identifies the specific sales order from the web address and simultaneously gathers all related records, including:

* Sales Quotations
* Delivery records
* Invoices
* Returns

3. Displaying Information: The page populates four distinct sections, each containing a table of relevant documents.
4. Navigation: You can switch between the "Details" view and this "Related Documents" view using the navigation tabs at the top of the page.
5. Drill-down Capability: Within the tables, you can click on specific document numbers or journal entries to jump directly to the detailed view of that specific record.

1.3 Key Concepts

– Sales Quotation: The initial price proposal sent to a customer before the order is finalized.

– Sales Deliveries: Records tracking the physical shipment of goods, including dates and status updates.

– Sales Invoices: Financial documents detailing the amount billed, payments received, and outstanding balances.

– Sales Order Returns: Records of items sent back by the customer, including approval status and any associated refunds.

- Journal: A financial record linked to documents (like invoices or returns) that tracks the accounting impact of that transaction.
- Workflow State: The current status of a document (e.g., Draft, Approved, or Delivered), helping you understand where a document sits in the business process.

1.4 Business Value

- Improved Efficiency: Staff no longer need to navigate to separate modules to find related documents; everything is linked to the original sales order.
- Enhanced Visibility: By seeing the full history—from quote to invoice and potential returns—users can quickly identify bottlenecks or discrepancies in the sales process.
- Better Customer Service: Support teams can provide immediate, accurate answers to customer inquiries regarding the status of their orders, deliveries, or billing without needing to switch screens.
- Simplified Auditing: Having all related documents grouped together makes it significantly easier to track the financial and operational trail of any given sale.

2. Logic

2.1 Overview

The Sales Order Details page provides a comprehensive view of a specific sales order. It acts as a central hub where you can see the primary order information alongside its associated history, including quotations, deliveries, invoices, and any returns. This allows staff to track the entire lifecycle of a sale from a single screen.

2.2 Step-by-Step Flow

1. Authentication Check: When you open the page, the system verifies your login session. If you are not logged in, you will be automatically redirected to the login screen.
2. Load Primary Order Data: The system retrieves the core details of the sales order (such as the customer, warehouse, dates, and status) based on the order ID in the web address.
3. Parallel Data Retrieval: Once the main order is loaded, the system simultaneously fetches all related records:

* Quotations: Any price quotes associated with this order.

* Deliveries: A log of all shipments made against the order.

* Invoices: A record of all billing documents and payment statuses.

* Returns: Any items sent back by the customer.

4.

Display: The retrieved information is organized into clear, readable tables and summary sections for each category, ensuring you have a complete picture of the order's progress.

2.3 Key Concepts

- Sales Order: The primary document representing a customer's request for goods or services.
- Quotation: A formal document providing the customer with pricing and terms before the order is finalized.
- Delivery: A record confirming that items from the order have been shipped or handed over to the customer.
- Invoice: A financial document requesting payment for the goods or services provided.
- Return: A record of items that were sent back by the customer after delivery.
- Workflow Status: A visual indicator (such as "Draft," "Approved," or "Delivered") that shows the current stage of the order in your business process.

2.4 Business Value

This feature eliminates the need to navigate between multiple screens to piece together the history of a sale. By consolidating quotations, deliveries, invoices, and returns into one view, your team can:

* Improve Customer Service: Quickly answer customer questions about their order status, billing, or returns without searching through different modules.

* Increase Efficiency: Reduce the time spent manually cross-referencing documents.

* Enhance Accuracy: Ensure that all stakeholders are looking at the same, up-to-date information regarding the order's financial and logistical status.

3. Data

3.1 Overview

The Sales Order Details page serves as a centralized hub for managing the entire lifecycle of a sales transaction. Instead of navigating through multiple screens, users can view the primary order information and access specific tabs to track related activities—such as quotations, deliveries, invoices, and returns—all in one place.

3.2 Step-by-Step Flow

1. Primary Order View: When you open a Sales Order, the system displays the core details, including the customer information, delivery address, salesperson, and the current workflow status (e.g., Draft, Approved, or Delivered).
2. Itemized Breakdown: The page lists all products associated with the order, showing the quantity ordered versus the quantity delivered, along with pricing, discounts, and total amounts.

3. Quotation Tab: You can view all price quotes associated with the order, including their current status, total value, and key dates.
4. Delivery Tab: This section tracks the fulfillment process, showing when items were shipped, their current status, and the associated journal records.
5. Invoice Tab: This tab provides a financial summary, detailing the invoice date, payment status, amounts paid, and any outstanding balances.
6. Returns Tab: If any items are sent back, this section tracks the return process, including approval dates, receipt confirmation, and payment status for the return.

3.3 Key Concepts

- Sales Order: The master record that captures the agreement between the business and the customer, containing all items, pricing, and shipping details.
- Workflow Status: A visual indicator that shows the current stage of the order (e.g., whether it is still being drafted, has been approved, or is currently out for delivery).
- Tabbed Interface: A design approach that organizes related documents (Quotations, Deliveries, Invoices, Returns) into separate, easy-to-access sections within the same page.
- Journal: A record-keeping feature that tracks the financial or inventory movements associated with a specific transaction, such as a delivery or an invoice.

3.4 Business Value

This feature significantly improves operational efficiency by providing a "single source of truth" for any given sales order. By consolidating quotations, fulfillment, billing, and returns into one view, staff can quickly answer customer inquiries, resolve discrepancies, and monitor the financial health of an order without switching between different modules or reports.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order Return Details Page /sales_order_returns/[record_id]

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Order Return Details page provides a centralized view for managing the lifecycle of a customer return. It allows authorized users to track the status of returned items, verify financial details, and progress the return through various stages—from initial draft to final approval.

1.2 Step-by-Step Flow

1. Navigation: Users access the page via the Sales menu. A back button is available to return to the main list of sales order returns.
2. Viewing Details: The page displays key information, including the document reference number, associated sales order and invoice, customer details, warehouse destination, and relevant timestamps.
3. Workflow Management: A status bar at the top tracks the current state of the return (Draft, Received, Approved, or Cancelled). Users can perform actions based on the current state:

* Draft: Can be marked as "Received" or "Cancelled."

* Received: Can be "Approved" or "Cancelled."

* Cancelled: Can be "Reset" back to a Draft state.

4. Item Review: A detailed table lists all returned items, including SKU, product name, quantity, pricing, and the reason for the return. A footer row provides the total quantity of items returned.
5. Financial Summary: The page calculates and displays the financial impact of the return, including subtotal, discounts, tax, and the final total credit amount.
6. Confirmation: Any status change (Receive, Approve, Cancel, or Reset) triggers a confirmation modal to ensure accuracy before the system updates the record.

1.3 Key Concepts

- Workflow State: The current phase of the return process, which dictates which actions (buttons) are available to the user.
- Document Reference: A unique identifier for the return, which can be easily copied for reference in other systems or communications.
- Financial Summary: A breakdown of the credit value, ensuring transparency regarding how the final refund or credit amount was calculated.
- Status Modals: Pop-up windows that require user confirmation before finalizing a change to the return status, preventing accidental updates.

1.4 Business Value

- Operational Efficiency: By providing a clear, step-by-step workflow, the page reduces manual errors and ensures that returns are processed consistently.
- Financial Accuracy: The automated calculation of totals, taxes, and credit amounts ensures that the financial impact of every return is accurate and easy to audit.
- Improved Visibility: Centralizing all information—from the original sales order to the final approval date—allows staff to quickly answer customer inquiries and track the status of returned inventory.
- Controlled Process: The use of status-based actions ensures that inventory and accounting records are only updated at the appropriate time, maintaining the integrity of the ERP data.

2. Logic

2.1 Overview

The Sales Order Return Details page provides a centralized view for managing returned items. It allows authorized users to view comprehensive information about a return—including financial totals, itemized lists, and audit details—and manage the return's lifecycle through a guided workflow.

2.2 Step-by-Step Flow

1. Authentication Check: When a user navigates to the page, the system verifies their session. If the user is not logged in, they are automatically redirected to the login screen.
2. Data Retrieval: The system fetches all relevant details for the specific return record, including document references, financial summaries, and the current status of the return.
3. Page Rendering: The information is organized into three main sections:

* Header Panel: Displays key metadata like document numbers, dates, customer/warehouse information, and notes.

* Financial Panels: Shows subtotals, taxes, discounts, and credit allocations.

* Items Table: Lists each returned product, including quantities, pricing, and the reason for the return.

4. Workflow Management: Depending on the current status (e.g., Draft, Received, Approved, or Cancelled), the system displays appropriate action buttons.
5. Action Confirmation: When a user clicks an action (like "Approve" or "Receive"), a confirmation dialog appears to prevent accidental changes.
6. System Update: Upon confirmation, the system updates the return status and refreshes the page to reflect the new state, including updating timestamps, journal entries, and available action buttons.

2.3 Key Concepts

- Workflow State: The current stage of the return process (Draft, Received, Approved, or Cancelled), which determines what actions a user can take.
- Audit Fields: Tracking information that records who updated the return and when, ensuring transparency and accountability.
- Confirmation Modal: A safety feature that requires the user to confirm an action before the system processes a status change.
- Financial Summary: A breakdown of the return's monetary value, including taxes, discounts, and the final credit amount to be applied.

2.4 Business Value

- Operational Efficiency: Provides a single source of truth for return data, reducing the need to cross-reference multiple documents.
- Error Reduction: The use of confirmation dialogs and automated status transitions prevents accidental processing errors.
- Improved Auditability: By automatically tracking updates and linking to journal entries, the system ensures that all financial adjustments are documented and traceable.
- Streamlined Process: The workflow-driven interface guides users through the necessary steps, ensuring that returns are handled consistently from initiation to final approval.

3. Data

3.1 Overview

The Sales Order Return Details page provides a comprehensive view of a specific product return request within the Lumi ERP system. This page acts as a central hub for staff to review the status, financial impact, and specific items associated with a return, ensuring that all information—from the original sales order to the final credit amount—is easily accessible and transparent.

3.2 Step-by-Step Flow

1. Data Retrieval: When a user opens a specific return record, the system gathers all relevant information, including the return header (dates, customer, warehouse, and status) and the list of returned items.
2. Information Aggregation: The system links the return to its original source documents, such as the original Sales Order, the associated Invoice, and the relevant accounting Journal.
3.

Calculation: The system automatically calculates the total quantity of items being returned to provide a quick summary at the bottom of the item list.

4. Display: The page presents the data in three distinct sections:

* Header Panel: Displays administrative details, status, and links to related records.

* Amount Panel: Breaks down the financial impact, including subtotals, discounts, taxes, and the final credit amount.

* Items Table: Lists each returned product, its condition, pricing, and the reason for the return.

3.3 Key Concepts

- Workflow State: The current stage of the return process (e.g., Draft, Approved, or Cancelled), which determines which action buttons are available to the user.
- Financial Breakdown: A clear view of how the return affects the customer's balance, including adjustments for discounts, taxes, and credit notes.
- Traceability: The ability to click through from the return page directly to related documents like the original Sales Order, Invoice, or Product details.
- Return Reason: Specific documentation for each item explaining why it was returned, which helps in tracking quality issues or customer preferences.

3.4 Business Value

This feature streamlines the returns process by eliminating the need to manually cross-reference multiple documents. By centralizing all financial and logistical data in one view, staff can process returns faster, reduce errors in credit calculations, and maintain clear communication with customers regarding their return status.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/taxes

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The `GET /api/taxes` feature provides a flexible way for the system to retrieve tax information. It is designed to support two primary use cases: displaying a comprehensive list of taxes (for management pages) and providing a simplified list of active taxes (for dropdown menus). The system includes built-in safeguards for date ranges and pagination to ensure performance and data accuracy.

1.2 Step-by-Step Flow

1. Request Processing: The system receives the request and identifies the desired view (either a full list or a simplified dropdown list).
2. Specific Lookup: If a specific tax ID is provided, the system searches for that exact record. If it is not found, an error is returned.
3. Date Normalization: If date filters are used, the system automatically adjusts the range to ensure it covers a maximum of 31 days. If only one date is provided, the system calculates the missing start or end date to complete the 31-day window.
4. Filtering: The system applies any requested filters, such as whether the tax is currently active and whether to filter by the creation date or the last updated date.
5. Data Retrieval:

* If the "options" view is requested, the system returns a minimal list of active taxes suitable for dropdowns.

* If the standard "list" view is requested, the system returns a paginated list of tax records based on the specified page number and limit.

1.3 Key Concepts

- View Types: Determines the level of detail returned. "List" provides full tax details for tables, while "Options" provides a slimmed-down version for selection menus.
- Date Normalization: An automated process that ensures date-based searches are always valid and restricted to a 31-day window to prevent system strain.
- Pagination: A method of breaking large amounts of data into smaller, manageable chunks (pages) to improve loading speeds.
- Active Status Filtering: Allows users to toggle between viewing all taxes, only active taxes, or only inactive taxes.

1.4 Business Value

This feature centralizes tax data management, ensuring that different parts of the application—such as reporting dashboards and data-entry forms—receive exactly the information they need in the most efficient format. By enforcing date ranges and pagination, the API maintains high performance even as the number of tax records grows, providing a reliable and responsive experience for end-users.

2. Data

2.1 Overview

The "List Available Taxes" feature provides a flexible way for the system to retrieve tax information. It is designed to serve two primary purposes: displaying a comprehensive list of taxes for administrative management and providing simplified, lightweight lists for dropdown menus in other parts of the application. The system includes built-in intelligence to filter, sort, and paginate data, ensuring that users only see the information they need.

2.2 Step-by-Step Flow

1. Request Identification: The system receives a request to fetch tax data. It first checks if a specific tax ID is provided; if so, it returns only that specific record.
2. Filtering: If no specific ID is provided, the system applies optional filters based on the user's request, such as whether the tax is currently active or if it falls within a specific date range (based on creation or update dates).
3. View Selection: The system determines the required format:

* Options View: If requested, it returns a simplified list containing only the tax names and IDs, optimized for dropdown menus.

* List View: By default, it returns a detailed, paginated list of taxes, including metadata like the total count of records to help with navigation.

4. Data Delivery: The system returns the requested data or provides an appropriate error message if the request was invalid, unauthorized, or if the specific tax ID could not be found.

2.3 Key Concepts

– Pagination: A method of breaking large amounts of data into smaller, manageable pages to improve performance and readability.

– Filtering: The ability to narrow down results based on specific criteria, such as active status or date ranges.

– View Modes: Different ways of presenting data; "List" provides full details for tables, while "Options" provides minimal data for selection menus.

–

Metadata: Supplemental information returned with the data (such as the total number of records) that helps the application interface display information correctly.

2.4 Business Value

This feature streamlines tax management by ensuring that the application remains responsive even as the number of tax records grows. By offering both detailed lists and simplified dropdown options, it improves the user experience across different parts of the ERP system. Furthermore, the robust filtering and date-range capabilities allow finance teams to quickly audit or locate specific tax configurations, reducing manual effort and increasing operational efficiency.

BUSINESS REQUIREMENTS DOCUMENT

PUT /company/:id

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

The "Update Company" feature allows authorized users to modify the details of an existing company record within the Lumi ERP system. This ensures that information such as company names, tax identification numbers, and addresses remain accurate and up-to-date as business needs change.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user has the necessary permissions to perform updates. If the user is not logged in or lacks authorization, the request is rejected.
2. Record Verification: The system searches for the specific company using the provided ID. If no company is found with that ID, the system notifies the user that the record does not exist.
3. Business Rule Validation: The system checks if the new tax ID (if provided) is already being used by another company. If a conflict is found, the update is blocked to prevent duplicate or invalid data.
4. Data Update: Once all checks pass, the system updates the company's information and records the exact time the change was made.
5. Confirmation: The system returns the newly updated company details to confirm that the changes were successfully saved.

1.3 Key Concepts

- Authentication: A security gate that ensures only verified users can modify sensitive company data.
- Validation: A safety check that ensures the information being saved is correct and does not conflict with existing records (such as ensuring two companies don't share the same tax ID).
- Record ID: A unique identifier used to ensure the system is updating the correct company profile.
- Timestamping: An automated process that logs when a record was last modified, providing an audit trail for data changes.

1.4 Business Value

This feature provides a reliable and controlled way to maintain company data integrity. By enforcing business rules during the update process, the system prevents data entry errors and duplicates, ensuring that the ERP remains a "single source of truth" for organizational information. This reduces administrative overhead and improves the accuracy of reporting and financial operations.

2. Data

2.1 Overview

The "Update Company" feature allows authorized users to modify the details of an existing company record within the Lumi ERP system. This ensures that information such as company names, tax identifiers, and addresses remains current and accurate. The system automatically tracks when these changes occur by updating a timestamp on the record.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to update a specific company, identified by its unique ID, along with the new information (name, tax ID, and address).
2. Verification: The system checks the database to confirm that a company with the provided ID actually exists.
3. Data Update: If the company is found, the system updates the record with the new details and automatically records the current date and time as the "last updated" timestamp.
4. Validation Check: The system ensures the update adheres to business rules—specifically, it checks that the provided tax ID does not conflict with another existing company.
5. Confirmation: Once the update is successfully saved, the system retrieves and returns the updated company information to confirm the changes.
6. Error Handling: If the company ID is not found, or if there is a conflict (such as a duplicate tax ID), the system will return an appropriate error message to the user.

2.3 Key Concepts

- Unique Identifier: A permanent, system-generated code used to ensure the correct company record is being modified.
- Tax ID Validation: A business rule that prevents two different companies from sharing the same tax identification number, ensuring data integrity.
- Timestamping: An automated feature that logs the exact time of the most recent update, providing an audit trail for record changes.
- Error Handling: A protective mechanism that informs the user if an update cannot be completed due to missing records or invalid data.

2.4 Business Value

This feature provides the flexibility needed to maintain accurate master data within the ERP. By allowing seamless updates to company profiles, the business can ensure that reporting, invoicing, and compliance activities are always based on the most current information. Furthermore, the built-in validation rules prevent data entry errors, such as duplicate tax IDs, which helps maintain a clean and reliable database.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/payment-type

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get Payment Types" feature provides a way for the system to retrieve a list of all payment methods available to a specific company (such as cash, card, or vouchers). This list is used by the payment panel to display the correct options to users during a sale. The feature is designed to be secure, automatically scoping results to the logged-in user's company, and includes tools to help manage large lists of payment types efficiently.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to fetch payment types. It automatically identifies the company associated with the logged-in user to ensure data privacy.
2. Parameter Processing: The system checks for any optional filters (such as whether to show only active payment types or specific categories like "card" or "cash") and pagination settings (how many items to show and where to start in the list).
3. Data Retrieval: The system searches the database for all payment types belonging to that company, applying any requested filters.
4. Sorting and Pagination: The results are automatically sorted alphabetically by name. The system then calculates the total number of available items and prepares the specific "page" of results requested.
5. Response: The system returns the list of payment types along with the total count of items found. If the request is invalid or the user is not authorized, the system returns an appropriate error message.

1.3 Key Concepts

- Filtering: The ability to narrow down the list of payment types based on their status (active vs. inactive) or their specific category (e.g., cash, card, or voucher).
- Pagination: A method used to break a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Scoping: A security measure that ensures users can only see payment types that belong to their own company, preventing access to data from other organizations.
- Metadata: Additional information provided with the list, specifically the "total count," which helps the user interface know how many pages of data are available.

1.4 Business Value

This feature ensures that the payment panel is always populated with accurate, relevant, and company-specific payment options. By supporting filtering and pagination, the system remains fast and responsive even as a

company grows and adds more payment methods. This creates a seamless and reliable checkout experience for staff, reducing errors and ensuring that only valid, active payment methods are presented during a transaction.

2. Data

2.1 Overview

The `GET /api/payment-types` feature provides a secure way for the system to retrieve a list of payment methods (such as cash, card, or vouchers) configured for a specific company. This list is used by the payment panel to determine which options are available to a customer during a sale. The API automatically identifies the user's company based on their login session, ensuring that businesses only see their own configured payment types.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies the user's session to identify which company is making the request.
2. Parameter Validation: The system checks the request for any pagination settings (limit and offset). If these numbers are negative, the request is rejected.
3. Data Filtering: The system applies optional filters provided by the user, such as whether to show only "active" payment types or to filter by a specific "kind" (e.g., only "card" payments).
4. Sorting: The system organizes the resulting list alphabetically by name.
5. Pagination: The system calculates the total number of available records and retrieves only the specific "page" of results requested.
6. Response: The system returns the filtered, sorted, and paginated list of payment types along with metadata (total count and current page information) to the user.

2.3 Key Concepts

- Company Context: The API automatically scopes data to the authenticated user's organization, removing the need for the user to manually specify their company ID.
- Pagination: A method of breaking large lists into smaller, manageable chunks using a "limit" (how many items to show) and an "offset" (where to start in the list).
- Filtering: The ability to narrow down the results based on specific criteria, such as status (active/inactive) or payment category (cash, card, etc.).
- Metadata: Additional information returned with the data, such as the total number of records found, which helps the front-end interface display navigation controls correctly.

2.4 Business Value

This feature ensures that the payment interface is always accurate, performant, and secure. By automatically scoping data to the company, it prevents data leakage between different organizations. The inclusion of filtering and pagination ensures that even companies with a large number of payment methods can load the payment panel quickly and navigate through their options efficiently.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/payment-type-mappings

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of payment types that have been assigned to specific stores. It allows users to see which payment methods are currently active or inactive for their business locations. The information is automatically restricted to the user's own company, ensuring data security and relevance.

1.2 Step-by-Step Flow

1. Authentication: The system identifies the user and automatically locks the request to their specific company.
2. Parameter Collection: The system gathers any optional filters provided by the user, such as a specific store, a specific payment type, or the active status of the mapping.
3. Pagination Setup: The system checks if the user requested a specific number of results (limit) or a starting point (offset). If not provided, it defaults to showing the first 20 results.
4. Data Retrieval: The system searches the database for all mappings that match the user's company and the selected filters.
5. Ordering: The results are organized by the date they were created, starting with the oldest entries.
6. Response: The system returns the requested list of mappings along with a total count of all available records to help with navigation.

1.3 Key Concepts

- Payment Type Mapping: The link between a specific store and a payment method (e.g., credit card, cash, or digital wallet) that determines if that method is available for use at that location.
- Filtering: The ability to narrow down the list by selecting a specific store, a specific payment type, or by viewing only active/inactive mappings.
- Pagination: A method of breaking a large list of data into smaller, manageable pages to improve performance and readability.
- Scope: A security measure that ensures users can only view data belonging to their own company.

1.4 Business Value

This feature enables store managers and administrators to easily audit and manage payment configurations across their organization. By providing a clear view of which payment methods are enabled at which locations, businesses can ensure their point-of-sale systems are correctly configured, troubleshoot payment issues, and maintain consistency across all store branches.

2. Data

2.1 Overview

The `GET /api/payment-type-mappings` feature provides a way to retrieve a list of payment methods that have been assigned to specific stores within your company. This tool allows you to see which payment types are currently active or inactive for each store, helping you manage your payment configurations efficiently. The system automatically ensures that you only see data relevant to your own company.

2.2 Step-by-Step Flow

1. Authentication Check: The system identifies your company automatically based on your login credentials, ensuring you only access your own organization's data.
2. Applying Filters: You can narrow down the list by providing specific criteria, such as a particular store, a specific payment type, or the current status (active/inactive).
3. Counting Records: The system calculates the total number of records that match your filters to help with navigation.
4. Sorting and Pagination: The system organizes the results by the date they were created (oldest to newest) and breaks the list into manageable pages based on your requested limit and offset.
5. Data Delivery: The system returns the requested list of mappings along with metadata (such as the total count) to help your interface display the information correctly.

2.3 Key Concepts

- Payment Type Mapping: A record that links a specific payment method (like Credit Card or Cash) to a specific store location.
- Filtering: The ability to search for specific records by store, payment type, or status without having to scroll through the entire list.
- Pagination: A method of displaying large amounts of data in smaller, easier-to-read chunks (pages) to improve performance and usability.
- Metadata: Additional information provided with your results, such as the total number of items found, which helps the application know how many pages of data exist.

2.4 Business Value

This feature provides transparency into how payment methods are distributed across your retail locations. By allowing users to filter and view these mappings, the business can:

* Ensure Accuracy: Quickly verify that the correct payment methods are enabled for the right stores.

* Improve Efficiency: Easily identify and update the status of payment types across the organization.

* Maintain Control: Provide a secure, scoped view of configuration data that is restricted to the authenticated user's company, preventing unauthorized access to other organizations' settings.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/areas?area_type=village

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of villages from the system. It is designed to be flexible, allowing users to search for specific villages by name or narrow down the results based on their geographical location (such as by province, regency, or district). To ensure the system remains fast and responsive, the results are delivered in manageable chunks (pages).

1.2 Step-by-Step Flow

1. Request Validation: The system checks the request to ensure it is specifically asking for "villages." If any other area type is requested, the system will return an error.
2. Filter Extraction: The system identifies any search criteria provided, such as a specific name or a parent location (province, regency, or district), and determines which page of results is being requested.
3. Data Retrieval: The system searches the database for all entries categorized as "villages" that match the provided filters.
4. Sorting and Pagination: The system organizes the matching villages alphabetically by name and applies pagination settings to return only the requested number of results per page.
5. Response: The system sends the filtered, sorted, and paginated list of villages back to the user. If an unexpected error occurs during this process, the system provides a standard error notification.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.
- Filtering: The ability to narrow down a large dataset by specific criteria, such as searching for a village by name or by its parent administrative region.
- Hierarchy: The geographical structure of the system, where villages are linked to districts, which are linked to regencies, which are linked to provinces.
- Query Parameters: Specific instructions included in the request (like "page number" or "district ID") that tell the system exactly what data to retrieve.

1.4 Business Value

This feature enables efficient navigation and data management within the Lumi ERP system. By allowing users to filter and paginate village data, it reduces the time spent searching for specific locations and prevents the system from being overwhelmed by large amounts of data at once. This ensures that administrative tasks involving geographical data are faster, more accurate, and easier to manage.

2. Data

2.1 Overview

This feature provides a way to retrieve a list of villages from the system. It is designed to be flexible, allowing users to search for specific villages by name or narrow down the results based on their geographic location (such as by district, regency, or province). To ensure the system remains fast and easy to navigate, the results are returned in smaller, manageable chunks (pagination) and are automatically sorted alphabetically by name.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to list villages. It automatically filters the database to only include records categorized as "village."
2. Applying Filters: The system checks for any optional search criteria provided:

– If a name is provided, it searches for villages that contain that text.

– If a geographic ID (province, regency, or district) is provided, the system traverses the location hierarchy to find only the villages belonging to that specific area.

3. Counting Results: The system calculates the total number of villages that match the applied filters. This information is used to help the user understand how many pages of results are available.
4. Sorting and Pagination: The system sorts the filtered list alphabetically by name. It then applies the requested page number and limit to return only the specific subset of data requested.
5. Response: The final list of villages is returned to the user.

2.3 Key Concepts

– Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.

– Geographic Hierarchy: The relationship between different administrative levels (Province > Regency > District > Village), allowing the system to filter villages based on their parent location.

– Filtering: The ability to narrow down a large dataset based on specific criteria, such as a partial name match or a specific administrative region.

– Sorting: The process of organizing the final list in a specific order—in this case, alphabetically by village name.

2.4 Business Value

This feature simplifies data management for the Lumi ERP by allowing users to quickly locate specific villages without having to scroll through an entire database. By supporting hierarchical filtering (province/regency/district),

it enables regional managers and administrators to generate targeted reports or perform data entry for specific areas efficiently. The inclusion of pagination ensures that the application remains responsive and performs well, even as the number of villages in the system grows over time.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/geo/provinces

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a reliable way for the system to retrieve a list of provinces for a specific country. It is designed to populate dropdown menus in the user interface, ensuring that when a user selects a country, the system automatically displays the correct, active provinces associated with that country, sorted alphabetically for easy selection.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and has an active session. If the session is missing or invalid, the request is denied.
2. Input Validation: The system checks that a valid country identifier has been provided. If the identifier is missing or formatted incorrectly, the system returns an error.
3. Data Retrieval: The system searches the database for all active provinces linked to the provided country identifier.
4. Sorting and Formatting: The retrieved provinces are sorted alphabetically by name and prepared as a clean list of IDs and names.
5. Response: The system sends the final list of provinces back to the user interface to populate the dropdown menu.

1.3 Key Concepts

- Country Identifier: A unique code used to ensure the system fetches provinces for the exact country selected by the user.
- Active Status: The system only retrieves provinces marked as "active," ensuring that outdated or discontinued regions do not appear in the dropdown.
- Cascading Filter: A design pattern where selecting an option in one menu (the country) automatically updates the available options in the next menu (the province).
- Alphabetical Sorting: The list is automatically organized from A to Z to improve the user experience when searching for a specific province.

1.4 Business Value

This feature streamlines data entry for users by providing accurate, context-aware dropdown options. By automating the province selection based on the chosen country, it reduces manual input errors, ensures data consistency across the ERP system, and creates a faster, more intuitive experience for users managing geographic information.

2. Data

2.1 Overview

This feature provides a reliable way for the Lumi ERP system to populate "Province" dropdown menus. When a user selects a country, the system automatically retrieves a clean, alphabetized list of all active provinces associated with that specific country. This ensures that users are only presented with valid, current options, improving data accuracy during address entry or location-based filtering.

2.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is currently logged in and authorized to access the data.
2. Input Validation: The system checks that a valid country identifier has been provided. If the identifier is missing or formatted incorrectly, the request is rejected.
3. Data Retrieval: The system searches the database for all provinces linked to the requested country that are marked as "active."
4. Sorting: The retrieved list is organized alphabetically by name to ensure a user-friendly experience.
5. Response: The system sends the final list of provinces back to the user interface to populate the dropdown menu. If an unexpected error occurs during this process, the system logs the issue and notifies the user that a server error has occurred.

2.3 Key Concepts

- Active Status: A filter that ensures only currently supported or valid provinces are displayed, hiding any that may be deprecated or inactive.
- Cascading Selection: A design pattern where the options in one dropdown (Provinces) are automatically updated based on the selection made in another (Country).
- Alphabetical Sorting: The list is automatically ordered from A to Z, making it easier for users to find the specific province they need.
- Validation: A safety step that ensures the system only processes requests with correct information, preventing errors caused by incomplete or malformed data.

2.4 Business Value

- Improved Data Integrity: By filtering for "active" provinces, the system prevents users from selecting outdated or invalid locations.
- Enhanced User Experience: Providing an alphabetized, filtered list reduces manual searching and minimizes user error during data entry.
-

Operational Efficiency: Automating the population of location dropdowns ensures that the application remains responsive and consistent across all modules that require address or geographic information.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/geo/regencies

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of regencies or municipalities based on a selected province. It is designed to power "cascading" dropdown menus, where selecting a province automatically updates the available options in the regency/municipality field. This ensures that users are only presented with relevant, accurate location data.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request that includes a specific province identifier.
2. Validation: The system checks to ensure the province identifier is present. If it is missing, the request is rejected with an error message.
3. Data Retrieval: The system searches the database for all active regencies or municipalities associated with the provided province ID.
4. Sorting: The retrieved list is organized alphabetically by name to ensure a user-friendly experience.
5. Response: The system returns the final list of regencies (including their unique IDs and names) to the user interface to populate the dropdown menu.

1.3 Key Concepts

- Cascading Dropdown: A user interface pattern where the options in one menu change dynamically based on the selection made in a previous menu.
- Province Identifier: A unique code used to pinpoint a specific province, ensuring the system fetches the correct corresponding regencies.
- Active Records: A filter applied to ensure that only currently valid or "live" locations are displayed to the user, hiding any outdated or inactive entries.

1.4 Business Value

- Improved Data Accuracy: By filtering regencies based on the selected province, the system prevents users from selecting invalid location combinations.
- Enhanced User Experience: Cascading menus reduce the number of options a user has to scroll through, making data entry faster and less prone to error.
- Standardization: This feature provides a consistent way for different parts of the Lumi ERP system to fetch location data, ensuring that address and area information remains uniform across the platform.

2. Data

2.1 Overview

This feature provides a way for the Lumi ERP system to retrieve a list of regencies (or municipalities) based on a selected province. It is designed to populate dropdown menus in the user interface, ensuring that when a user selects a province, they are presented with the correct, relevant, and active regencies for that specific area.

2.2 Step-by-Step Flow

1. Input Validation: The system receives a request containing a province identifier. It first checks to ensure this identifier is provided; if it is missing or empty, the request is rejected.
2. Data Retrieval: Once validated, the system searches the database for all regencies associated with that specific province.
3. Filtering: The system automatically filters the results to include only "active" regencies, ensuring that outdated or disabled options are not shown to the user.
4. Sorting: The retrieved list is organized alphabetically by name to provide a clean, user-friendly experience.
5. Response: The system formats the final list of regencies (providing their unique IDs and names) and sends them back to the application to populate the dropdown menu.

2.3 Key Concepts

- Regency: A geographical administrative division within a province, used here to help users narrow down location-based data.
- Active Status: A filter that ensures only currently valid or operational regencies are displayed, preventing users from selecting obsolete options.
- Cascading Selection: A design pattern where the options in one dropdown (Regency) are automatically updated based on the selection made in a previous dropdown (Province).
- Validation: A safety check performed at the start of the process to ensure the system has the necessary information to perform the search.

2.4 Business Value

This feature improves data accuracy and user efficiency by automating the "cascading" selection process. By ensuring that users only see active, relevant regencies for their chosen province, the system reduces manual data entry errors and streamlines the address or location-selection workflow within the ERP.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/geo/districts

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of districts based on a selected regency or municipality. It is designed to power "cascading dropdowns," where selecting a higher-level geographic area (the regency) automatically updates the available options in the district dropdown menu.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and has an active session. If not, the request is rejected.
2. Validation: The system checks that a valid regency identifier has been provided. If the identifier is missing or formatted incorrectly, the request is rejected.
3. Data Retrieval: The system searches the database for all active districts associated with the provided regency identifier.
4. Sorting and Formatting: The retrieved list of districts is sorted alphabetically by name and formatted into a simple list of IDs and names, which is then sent back to the user.

1.3 Key Concepts

- Cascading Dropdown: A user interface pattern where the options in one menu change based on the selection made in a previous menu (e.g., selecting a city updates the list of available districts).
- Regency ID: A unique reference code used to identify a specific regency or municipality, ensuring the system fetches the correct districts for that area.
- Active Status: The system only returns districts that are currently marked as "active," ensuring that users do not see outdated or discontinued locations.

1.4 Business Value

This feature improves data accuracy and user experience by automating geographic selections. By ensuring that users only see relevant, active districts for their chosen regency, it reduces manual data entry errors and streamlines the process of filling out forms or setting up location-based configurations within the Lumi ERP system.

2. Data

2.1 Overview

This feature provides a way for the system to retrieve a list of districts to populate dropdown menus. When a user selects a specific regency (or municipality), the system will automatically fetch the relevant districts associated with that area. This ensures that users are only presented with accurate, active, and relevant location options.

2.2 Step-by-Step Flow

1. Request Validation: The system receives a request containing a specific regency identifier. It first checks to ensure this identifier is formatted correctly. If the format is invalid, the request is rejected.
2. Data Filtering: The system searches the database for all districts linked to the provided regency. It automatically filters out any districts that are marked as inactive.
3. Sorting: The resulting list of districts is organized alphabetically by name to make it easier for users to find what they need.
4. Data Delivery: The system returns a clean list containing only the necessary information—the unique ID and the name of each district—to be displayed in the dropdown menu.

2.3 Key Concepts

- Regency: A regional administrative division; in this context, it acts as the "parent" category used to filter which districts appear in the list.
- Active Status: A safety filter that ensures only currently valid or "live" districts are shown to the user, hiding any that have been retired or disabled.
- Cascading Filter: A design pattern where the options in one dropdown (Districts) are automatically updated based on the selection made in a previous dropdown (Regency).

2.4 Business Value

This feature improves data accuracy and user experience by preventing users from selecting outdated or irrelevant locations. By automating the district list based on the selected regency, it reduces manual data entry errors and streamlines the address-selection process within the ERP system.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/areas?area_type=province

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of provinces stored in the Lumi ERP database. It is designed to be efficient by allowing users to search for specific provinces by name and view the results in manageable chunks (pages) rather than loading the entire list at once.

1.2 Step-by-Step Flow

1. Security Check: The system first verifies that the user is logged in and authorized to access the data. If the session is invalid, the request is rejected.
2. Validation: The system checks the request to ensure the user is specifically asking for "provinces." If any other area type is requested, the system will return an error.
3. Filtering and Sorting: The system applies any name-based search criteria provided by the user. It then organizes the resulting list alphabetically by name.
4. Pagination: The system breaks the results into pages based on the requested page number and the number of items per page. If no specific page settings are provided, it defaults to showing 20 items per page.
5. Data Delivery: The system returns the requested list of provinces, including details such as the province name, ID, and country code.

1.3 Key Concepts

- Pagination: A method of splitting a large list of data into smaller, numbered pages to improve performance and readability.
- Filtering: The ability to narrow down a large list of results by searching for a specific name or category.
- Authentication: A security step that ensures only verified users can access the information.
- Query Parameters: Specific instructions sent with a request (like "page number" or "search name") that tell the system exactly what subset of data to retrieve.

1.4 Business Value

This feature improves the usability of the Lumi ERP by allowing staff to quickly locate specific provinces without scrolling through long, unorganized lists. By implementing pagination, the system remains fast and responsive even as the number of provinces in the database grows over time.

2. Data

2.1 Overview

This feature provides a reliable way for the system to retrieve a list of provinces. It is designed to handle large amounts of data efficiently by breaking the results into manageable pages and allowing users to search for specific provinces by name.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request specifically asking for "provinces."
2. Filtering: If a name is provided, the system searches for provinces that match that name (even if only a part of the name is entered).
3. Sorting: The system automatically organizes the resulting list in alphabetical order by name.
4. Pagination: The system calculates which specific "page" of results to show based on the requested page number and the number of items allowed per page.
5. Data Retrieval: The system fetches the requested subset of data along with the total count of all available provinces.
6. Response: The system returns the list of provinces along with metadata (such as the current page and total count) to the user.

2.3 Key Concepts

- Pagination: A method of splitting a large list of items into smaller, numbered pages to improve performance and readability.
- Filtering: The ability to narrow down a large list of results by providing specific criteria, such as a partial name match.
- Metadata: Additional information provided with the data, such as the total number of records found, which helps the user interface display navigation controls (like "Next" or "Previous" buttons).
- Sorting: The automatic arrangement of data in a specific order—in this case, alphabetically by name—to ensure consistency.

2.4 Business Value

This feature improves the user experience by ensuring that province selection is fast and intuitive. By implementing pagination and search, we prevent the system from being overwhelmed by large datasets, ensuring that users can quickly find the specific province they need without scrolling through long, unorganized lists. This standardized approach also ensures that all parts of the application display province data consistently.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/areas?area_type=regency

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of regencies. It is designed to be flexible, allowing users to search for specific regencies by name or filter them by their parent province. To ensure the system remains fast and responsive, the results are delivered in smaller, manageable chunks (pages) rather than all at once.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to access the data. If not, the request is rejected.
2. Parameter Processing: The system collects the search criteria (such as the name of the regency or the province ID) and the pagination settings (which page to show and how many items per page).
3. Validation: The system confirms that the request is specifically asking for "regencies." If any other area type is requested, the system returns an error.
4. Data Retrieval: The system searches the database using the provided filters, sorts the results alphabetically by name, and applies the pagination settings to return the correct subset of data.
5. Response: The system sends the requested list of regencies back to the user. If an unexpected error occurs during this process, the system notifies the user that a server error has occurred.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.
- Filtering: The ability to narrow down search results based on specific criteria, such as searching for a regency by its name or its parent province.
- Authentication: A security step that ensures only verified users can access the information.
- Sorting: The automatic organization of the final list in alphabetical order (A-Z) by name to make it easier for users to find what they need.

1.4 Business Value

This feature streamlines administrative tasks by allowing users to quickly locate specific regencies within the system. By supporting filtering and pagination, it prevents the system from being overwhelmed by large amounts of data, ensuring that the application remains fast and user-friendly even as the database grows. This provides a reliable and efficient way to manage geographical data across the platform.

2. Data

2.1 Overview

This feature provides a way for the system to retrieve a list of "regencies" (a specific type of administrative area) from the Lumi ERP database. To ensure the system remains fast and easy to navigate, the results are returned in smaller, manageable chunks (pagination) and can be narrowed down using specific search criteria.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to list areas, specifically filtered to show only "regencies."
2. Applying Filters: The system checks for optional search criteria provided by the user:

* Name: If a name is provided, the system searches for regencies that contain that text (e.g., searching "Ilir" will return "Ilir Barat" and "Ilir Timur").

* Province: If a province is specified, the system limits the results to only those regencies belonging to that specific province.

3. Sorting: The resulting list is automatically organized in alphabetical order by the regency name.
4. Pagination: The system calculates which "page" of data to show based on the requested page number and the limit (number of items per page).
5. Data Retrieval: The system fetches the requested subset of regencies and calculates the total number of matching records available.
6. Response: The system returns the list of regencies along with metadata (total count, current page, and limit) to help the user interface display the information correctly.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, numbered pages to improve performance and readability.
- Filtering: The ability to narrow down a large dataset based on specific criteria, such as searching by name or grouping by a parent area (province).
- Metadata: Additional information provided with the data, such as the total number of records found, which helps the application know how many pages of results exist.
- Partial Match: A search feature where the system finds results that contain the search term anywhere within the name, rather than requiring an exact match.

2.4 Business Value

This feature enables efficient data management within the Lumi ERP. By allowing users to search and filter regencies, it reduces the time spent manually looking through long lists. Furthermore, the use of pagination

ensures that the application remains responsive and performs well, even as the number of regencies in the database grows over time.

BUSINESS REQUIREMENTS DOCUMENT

Deactivate Customer Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Deactivate Customer Modal is a safety feature designed to prevent accidental changes to your customer records. When you choose to deactivate a customer, this pop-up window appears to ask for a final confirmation, ensuring that you intentionally want to change the customer's status to "inactive" before the system processes the request.

1.2 Step-by-Step Flow

1. Initiation: The user triggers the deactivation process for a specific customer.
2. Confirmation Prompt: A modal window appears displaying the name of the customer and asking for confirmation to proceed.
3. User Decision:

* To Proceed: The user clicks the "OK" button. The system then updates the customer's status to inactive and closes the window.

* To Cancel: The user clicks the "Cancel" button or the "X" icon in the corner. The window closes immediately, and no changes are made to the customer's status.

4. Processing State: While the system is updating the customer's status, the "OK" button is temporarily disabled to prevent duplicate requests.

1.3 Key Concepts

- Deactivation: A status change that marks a customer as inactive within the system.
- Confirmation Modal: A secondary window that requires user interaction to verify an action before it is finalized.
- Safety Lock: A feature that disables the "OK" button during processing to ensure the system remains stable and prevents accidental double-clicks.
- Graceful Exit: The ability to close the window at any time without affecting the customer's data.

1.4 Business Value

This feature reduces the risk of human error by providing a "safety net" for sensitive administrative actions. By requiring a deliberate confirmation, it ensures that customer records are only deactivated when intended, maintaining the integrity of your customer database and preventing unnecessary disruptions to business operations.

2. Logic

2.1

Overview

The Deactivate Customer Modal is a safety feature designed to prevent accidental changes to customer records. When you choose to deactivate a customer, this modal appears to confirm your intent. It ensures that the system only updates the customer's status after you have explicitly verified the action, while also providing feedback if the system encounters any issues during the process.

2.2 Step-by-Step Flow

1. Initiation: You select a customer and trigger the deactivation process, which opens the confirmation modal.
2. Confirmation: The modal displays the name of the customer you are about to deactivate and asks for your final confirmation.
3. Processing: Once you click "OK," the system begins the deactivation request. During this time, the "OK" button is disabled to prevent you from accidentally sending the request multiple times.
4. Success: If the request is successful, the modal closes automatically, and the customer list refreshes to show the updated status.
5. Error Handling: If the system cannot complete the request (e.g., due to a connection issue), the modal remains open, and an error message is displayed so you know exactly what went wrong.

2.3 Key Concepts

- Deactivation: A status change that marks a customer as inactive in the system without deleting their record.
- Submission Protection: A safeguard that disables the "OK" button while the system is working, ensuring that only one request is processed at a time.
- Error Feedback: A clear notification displayed within the modal if the system fails to update the customer status, allowing you to address the issue before trying again.
- List Refresh: An automatic update of your customer dashboard that ensures you are always viewing the most current information after a change is made.

2.4 Business Value

This feature provides a controlled and reliable way to manage customer statuses. By requiring a confirmation step, it reduces the risk of human error. Additionally, the built-in error handling and submission protection ensure that the system remains stable and that users are always informed about the outcome of their actions, leading to more accurate data management within the ERP.

3. Data

3.1 Overview

The Deactivate Customer Modal is a safety feature designed to prevent accidental changes to your customer records. When you choose to deactivate a customer, this modal appears to confirm your intent, ensuring that you are modifying the correct account before the system processes the change.

3.2 Step-by-Step Flow

1. Selection: You select a specific customer from your list to deactivate.
2. Data Retrieval: The system identifies the selected customer’s unique ID, their name, and their current status to ensure the request is accurate.
3. Confirmation: A modal window displays the customer's name, asking you to confirm that you wish to proceed with the deactivation.
4. Processing: Once you confirm, the system sends a request to update that specific customer's status to "inactive."

3.3 Key Concepts

- Customer Selection: The specific record identified by the system to ensure the correct account is targeted for deactivation.
- Confirmation Modal: A pop-up window that acts as a final check to prevent errors or accidental clicks.
- Status Update: The final action taken by the system to change a customer's account from "active" to "inactive."

3.4 Business Value

This feature reduces the risk of human error by providing a clear "stop-and-think" moment before permanent changes are made to customer records. By verifying the customer's identity and status before processing, the system maintains data integrity and prevents the accidental deactivation of active business accounts.

BUSINESS REQUIREMENTS DOCUMENT

Address Filter Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Address Filter Modal is a popup tool designed to help users quickly narrow down customer lists based on specific location details. By providing a centralized interface to input address-related criteria, users can efficiently find customers located in specific regions, cities, or neighborhoods without needing to search through the entire database manually.

1.2 Step-by-Step Flow

1. Open the Modal: The user triggers the address filter popup from the main customer page.
2. Input Criteria: The user enters location details into the available fields, including Country (via dropdown), Province, Regency/Municipality, District, Village, Postal Code, and specific street address details.
3. Data Validation: As the user types, the system ensures the Postal Code field only accepts numeric characters to maintain data accuracy.
4. Refine or Reset:

* If the user wants to start over, they can click "Clear All" to instantly empty all fields.

* If the user decides not to filter, they can click "Close" to exit without saving changes.

5. Apply Filter: Once the desired criteria are entered, the user clicks "Apply." The system then uses these specific location values to filter the customer list and display the relevant results.

1.3 Key Concepts

- Filter Criteria: The specific data points (such as country, province, or postal code) used to narrow down a large list of customers to a smaller, more relevant group.
- Data Validation: A built-in safety check that prevents users from entering incorrect information—specifically, ensuring the Postal Code field only contains numbers.
- Clear All: A convenience function that resets the form, allowing the user to quickly discard current filters and begin a new search.
- Apply: The action that confirms the user's selections and triggers the system to update the customer view based on the provided address parameters.

1.4 Business Value

This feature significantly improves user productivity by reducing the time spent searching for specific customer records. By allowing for granular filtering—from broad country-level searches down to specific village or street addresses—the system enables staff to manage regional data more effectively, improve reporting accuracy, and streamline daily operations within the Lumi ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

User Details Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The User Details Modal is a centralized interface within the Lumi ERP system designed to manage customer information. It allows staff to view and update a comprehensive profile for a specific customer, ensuring that all necessary contact and demographic data is captured accurately in one place.

1.2 Step-by-Step Flow

1. Open the Modal: The user triggers the "User Details" window to view or modify an existing customer record.
2. Data Entry: The user fills in or updates various fields, including personal information (Name, Phone, Birthdate, Gender), professional details (Occupation, Company), and administrative data (Customer Code, Notes, Area/Region).
3. Real-Time Validation: As the user types or selects information, the system immediately checks for errors. Specifically, it ensures that mandatory fields—Name, Phone, and Store—are not left blank and that the Birthdate entered is a realistic, valid date.
4. Form Submission: Once all required fields are correctly populated, the "Save Changes" button becomes active.
5. Processing: Upon clicking "Save," the system sends the updated information to the server to finalize the record, and the modal closes automatically upon success.

1.3 Key Concepts

- Real-Time Validation: A feature that checks for errors while the user is still typing, providing immediate feedback so they can fix mistakes before attempting to save.
- Required Fields: Specific pieces of information (Name, Phone, and Store) that must be provided for the system to process the customer record successfully.
- Plausible Date Check: A safety mechanism that prevents the entry of impossible dates (e.g., a birthdate in the future) to ensure data integrity.
- Modal: A pop-up window that keeps the user focused on the task at hand without navigating away from their current screen.

1.4 Business Value

- Data Accuracy: By enforcing mandatory fields and validating dates at the point of entry, the system prevents incomplete or incorrect customer records from entering the database.
- Operational Efficiency: Providing a single, organized view for all customer details reduces the time staff spend searching for or updating information across different screens.
-

Improved Customer Management: With consistent data collection—such as tracking store assignments, occupations, and wholesale company affiliations—the business can better segment and serve its customer base.

BUSINESS REQUIREMENTS DOCUMENT

Customer Group Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Group Card is a dedicated section within the Lumi ERP interface designed to help you manage how customers are categorized. It provides a simple way to view or update a customer’s assigned group and offers quick access to create new groups if the one you need does not yet exist.

1.2 Step-by-Step Flow

1. View Header: The card is clearly identified by a "CUSTOMER GROUP" header and a visual icon, making it easy to locate within the customer profile.
2. Select Group: You can use the "Group" dropdown menu to see a list of all available categories and assign the customer to the appropriate one.
3. Create New Group: If you need to assign a customer to a group that isn't in the list, you can click the "New Group" button.
4. Manage via Modal: Clicking the "New Group" button opens a pop-up window (modal) where you can define and save a new customer group without leaving your current page.

1.3 Key Concepts

- Customer Group: A classification label used to organize customers, allowing for better reporting and targeted management.
- Dropdown Selection: A standard menu that displays all existing groups, ensuring you can quickly reassign a customer with a single click.
- Modal Window: A focused pop-up screen that allows you to perform a specific task—in this case, creating a new group—without navigating away from the customer's profile.

1.4 Business Value

This feature streamlines customer management by centralizing group assignments in one place. By allowing users to create new groups on the fly, it reduces administrative friction and ensures that customer data remains organized and up-to-date without requiring the user to switch between different areas of the software.

BUSINESS REQUIREMENTS DOCUMENT

Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Settings Card is a dedicated interface component designed to help you manage and update essential configuration details for a customer. It provides a clean, organized space within the Lumi ERP system to ensure that key settings—specifically tax-related information—are easily accessible and correctly applied to customer accounts.

1.2 Step-by-Step Flow

1. Initialization: When the card loads, the system automatically retrieves the latest list of available tax rates from the database to populate the selection menu.
2. Display: The card displays a clear "SETTINGS" header with an icon, grouping the configuration options together for easy identification.
3. Selection: You select the appropriate tax rate for the customer from the "Service Tax" dropdown menu.
4. Validation: As you make a selection, the system immediately checks to ensure a valid tax rate has been chosen. If the field is left empty, the system flags it to prevent incomplete data.
5. Saving: Once a valid selection is made, the system securely transmits the updated tax information to the customer's profile, ensuring the account settings remain accurate.

1.3 Key Concepts

- Service Tax: A specific configuration setting that determines which tax rate should be applied to a customer's transactions.
- Validation: An automated check performed by the system to ensure that required information is provided before a change is finalized.
- Dropdown Menu: A user-friendly interface element that allows you to choose a single option from a pre-defined list of available tax rates.

1.4 Business Value

This feature streamlines the customer onboarding and maintenance process by centralizing configuration management. By providing a dedicated, validated interface for tax settings, it reduces the risk of manual entry errors, ensures consistent tax application across customer accounts, and saves time for administrative staff by automating the retrieval and validation of tax data.

BUSINESS REQUIREMENTS DOCUMENT

TAX Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Tax Modal is a dedicated interface component within the Lumi ERP system designed to help users manage and update a customer's tax-related information. This feature provides a centralized, user-friendly window where staff can input and save essential tax identification numbers, ensuring that customer records remain accurate for financial and regulatory compliance.

1.2 Step-by-Step Flow

1. Access the Modal: The user opens the Tax Modal, which displays a clear header labeled "TAX" accompanied by a percentage icon to indicate its purpose.
2. Input Data: The user enters the relevant tax details into three specific fields: NPWP (Tax Identification Number), NPPKP (VAT-registered taxpayer number), and NITKU (Tax Identity Number).
3. Real-time Validation: As the user types, the system automatically checks the information. For example, if the NPWP number is entered, the system ensures it meets the required length to prevent common entry errors.
4. Submit Changes: Once the information is entered correctly, the user clicks the "Save Changes" button. If any errors are detected, the save button is disabled to prevent invalid data from being sent to the system.
5. Confirmation: Upon a successful save, the system updates the customer's profile with the new tax settings and closes the modal.

1.3 Key Concepts

- NPWP: The primary tax identification number used for identifying a taxpayer in the system.
- NPPKP: A specific identifier for customers who are registered for Value Added Tax (VAT).
- NITKU: A secondary tax identity number used for specific tax reporting requirements.
- Input Validation: An automated safety check that ensures data is formatted correctly before it is saved, reducing the risk of errors in financial records.

1.4 Business Value

This feature streamlines the administrative process of maintaining customer tax data. By providing a structured and validated input method, it reduces manual data entry errors and ensures that the ERP system holds reliable, up-to-date tax information. This consistency is critical for accurate invoicing, tax reporting, and maintaining compliance with local financial regulations.

BUSINESS REQUIREMENTS DOCUMENT

SAP Reporting Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The SAP Reporting Card is a new interface component designed for the Lumi ERP system. It provides a dedicated space for users to input and manage specific financial reporting details required for SAP integration. By centralizing these fields, the feature ensures that essential accounting data is captured accurately and consistently within the customer profile.

1.2 Step-by-Step Flow

1. Header Display: The user views the "SAP Reporting" section, which is clearly marked with a document icon to indicate its purpose as a data entry area for financial reporting.
2. Data Entry: The user enters information into three specific fields: Cost Center, Profit Center, and Assignment.
3. Real-time Validation: As the user types, the system immediately checks the input for accuracy. For example, if the Cost Center entry exceeds the allowed character limit, the system will display an error message right away.
4. Error Feedback: If any information is entered incorrectly, the system highlights the specific field with an error message, allowing the user to correct the data before proceeding.

1.3 Key Concepts

- Cost Center: A specific department or unit within an organization that incurs costs and is used for internal accounting and budget tracking.
- Profit Center: A business unit or division that is responsible for its own revenue and expenses, used to evaluate the profitability of different segments of the company.
- Assignment: A flexible field used to categorize or link financial transactions to specific projects, contracts, or internal tracking codes.
- Real-time Validation: A feature that checks the data as it is being typed, providing instant feedback to the user to prevent errors before the information is saved.

1.4 Business Value

This feature streamlines the data entry process for financial reporting by providing a clean, organized, and validated interface. By enforcing character limits and providing immediate feedback, it reduces the likelihood of data entry errors that could cause issues when syncing information with SAP. This ensures higher data integrity and saves time for users who would otherwise need to correct reporting discrepancies later in the accounting cycle.

BUSINESS REQUIREMENTS DOCUMENT

Addresses Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Addresses Card is a user interface component designed to help you manage and view a customer's contact locations. It provides a clear, organized table that lists all saved addresses, including their specific types (e.g., Home or Office) and contact details. The feature also includes a simple way to add new addresses directly through an interactive form.

1.2 Step-by-Step Flow

1. View Addresses: When you open the customer profile, the system automatically loads and displays all saved addresses in a table format.
2. Review Details: You can scan the table to see the address type, primary contact numbers, fax numbers, and indicators showing which address is designated as the "Main" or "Shipping" location.
3. Initiate New Entry: If you need to add a new location, click the "Add Address" button located below the table.
4. Enter Information: A form overlay will appear, allowing you to input the address type, phone numbers, and fax number.
5. Validation: As you type, the system checks your entries (such as ensuring phone numbers meet the required length) to prevent errors.
6. Save: Once the form is complete, you can submit the information, which saves the new address to the customer's record and closes the form.

1.3 Key Concepts

- Address Table: A structured list that organizes all customer locations, making it easy to compare contact details and status indicators at a glance.
- Status Indicators: Simple "Yes/No" markers that identify which address is the primary location and which is used for shipping, helping to avoid confusion.
- Form Validation: An automated check that runs while you are typing to ensure the information entered is accurate and complete before it is saved.
- Modal Overlay: A pop-up window that allows you to perform a specific task—like adding an address—without leaving the current page or losing your place.

1.4 Business Value

This feature streamlines customer data management by centralizing all location-based information in one place. By providing clear indicators for primary and shipping addresses, it reduces the risk of shipping errors or miscommunication. Additionally, the built-in validation and easy-to-use form ensure that customer records remain accurate and consistent, saving time for staff and improving the overall quality of the customer database.

BUSINESS REQUIREMENTS DOCUMENT

New Addresses Modal

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The New Address Modal is a user-friendly interface designed to help staff easily add new location details to a customer's profile within the Lumi ERP system. This pop-up window provides a structured form to capture essential contact and location information, ensuring that address data is consistent and accurate across the platform.

1.2 Step-by-Step Flow

1. Open the Modal: The user initiates the process, opening the "Address" modal.
2. Enter Basic Details: The user provides the address type (e.g., home, office) and geographic details like country and province.
3. Select Location Hierarchy: The user selects the specific regency, district, village, and postal code from provided dropdown menus to ensure precise location mapping.
4. Provide Street Address: The user enters the full street address in a dedicated multi-line text area.
5. Add Coordinates: The user inputs the latitude and longitude for precise digital mapping.
6. Enter Contact Information: The user provides primary and secondary phone numbers, as well as a fax number. The system automatically validates the phone numbers to ensure they follow the correct format.
7. Finalize: The user clicks "Save" to submit the data and close the modal, or clicks "Cancel" (or the "X" icon) to discard the entry and close the window without saving.

1.3 Key Concepts

- Form Validation: An automated check that ensures phone numbers are entered in a valid format before the system allows the information to be saved.
- Modal: A pop-up window that allows users to complete a specific task (like adding an address) without leaving their current page.
- Hierarchical Dropdowns: A series of selection menus (Regency, District, Village, Postal Code) that guide the user to select accurate location data step-by-step.
- Data Persistence: The process of saving the entered information into the customer's profile so it is available for future use.

1.4 Business Value

- Data Accuracy: By using dropdowns for location details and format validation for phone numbers, the system reduces human error and ensures high-quality, standardized address data.
- Operational Efficiency: The intuitive, guided form allows staff to quickly update customer profiles, reducing the time spent on manual data entry.
-

Improved Customer Service: Maintaining precise location and contact information enables better logistics, accurate shipping, and reliable communication with customers.

BUSINESS REQUIREMENTS DOCUMENT

New Customer Group Modal

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The New Customer Group modal is a focused interface within the Lumi ERP designed to help users quickly categorize customers. By providing a simple, dedicated form, this feature allows you to define and save new customer groups without navigating away from your current workspace.

1.2 Step-by-Step Flow

1. Initiation: The user opens the "New Customer Group" modal, which displays a clear title identifying its purpose.
2. Data Entry: The user enters the desired name for the new customer group into the required text field.
3. Validation: As the user types, the system automatically checks that the name field is not empty. If the field is left blank, an error message appears to guide the user.
4. Submission: Once a valid name is entered, the user clicks the "Save" button. The system processes the request and automatically closes the modal upon a successful save.
5. Cancellation: At any point before saving, the user can dismiss the modal using either the "Cancel" button or the "X" icon in the header, which will discard any unsaved changes.

1.3 Key Concepts

- Modal: A pop-up window that appears over the main application screen, allowing you to complete a specific task without leaving your current page.
- Validation: An automated check that ensures required information—in this case, the group name—is provided before the system allows the data to be saved.
- Mutation: The technical process of sending your new group information to the system's database to create the record.

1.4 Business Value

This feature streamlines the customer management process by reducing the time and effort required to organize your client base. By providing an intuitive, error-resistant interface, it ensures that customer data is categorized consistently and accurately, which helps maintain clean records and improves reporting capabilities within the Lumi ERP.

BUSINESS REQUIREMENTS DOCUMENT

New Franchise Purchase Order dropdown

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Franchise Purchase Order" dropdown is a navigation feature designed to streamline how users begin the process of creating new purchase orders. Instead of navigating through multiple screens, users can now select the specific type of purchase order they need directly from the inventory list page, ensuring they are directed to the correct entry form immediately.

1.2 Step-by-Step Flow

1. The user clicks the "New Franchise Purchase Order" button located on the inventory list page.
2. A menu appears, presenting the user with two options: "Standard (External)" or "Internal."
3. The user selects their desired option from the list.
4. The system automatically navigates the user to the specific creation page corresponding to their selection.
5. The menu closes automatically once the selection is made.

1.3 Key Concepts

- Standard (External) Purchase Order: A document used for ordering goods or services from outside vendors or suppliers.
- Internal Purchase Order: A document used for requesting goods or services from within the organization or between franchise locations.
- Dropdown Menu: A user interface element that allows the user to choose one value from a list, keeping the main screen clean and organized.

1.4 Business Value

This feature improves operational efficiency by reducing the number of clicks required to start a new task. By clearly distinguishing between "Standard" and "Internal" purchase orders at the point of entry, the system helps prevent user error and ensures that the correct workflow is initiated from the start, saving time and reducing administrative confusion.

BUSINESS REQUIREMENTS DOCUMENT

New Franchise Purchase Return Dropdown

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The new Franchise Purchase Return dropdown simplifies the process of initiating a return by allowing users to specify the type of return at the start. Instead of navigating through a generic page, users can now select whether they are processing an "Internal" return or a "Standard (External)" return directly from the inventory interface. This ensures the user is immediately directed to the correct form for their specific needs.

1.2 Step-by-Step Flow

1. The user clicks the "Add Franchise Purchase Return" button on the inventory page.
2. A menu appears, presenting two options: "Internal" and "Standard (External)."
3. If the user selects "Internal," the system redirects them to the dedicated form for internal franchise purchase returns.
4. If the user selects "Standard (External)," the system redirects them to the dedicated form for standard, external franchise purchase returns.

1.3 Key Concepts

- Internal Return: A return process specifically for items moving within the franchise network or internal organizational units.
- Standard (External) Return: A return process for items being sent back to external vendors or suppliers.
- Dropdown Navigation: A user interface element that acts as a shortcut, allowing the user to choose their destination before loading the next page.

1.4 Business Value

This feature improves operational efficiency by reducing the time spent navigating through menus or correcting errors caused by selecting the wrong return type. By clearly distinguishing between internal and external returns at the point of entry, the system ensures that data is captured in the correct format from the start, leading to more accurate inventory tracking and streamlined reporting.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Stock Order Menu Tab

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Order Menu is a centralized navigation component within the Lumi ERP system. It provides a clean, tabbed interface that allows users to quickly switch between different categories of stock orders. By organizing these categories into distinct views, the system ensures that users can efficiently manage inventory tasks relevant to their specific operational needs, such as warehouse management, retail sales, service requests, or internal work orders.

1.2 Step-by-Step Flow

1. Navigation: The user interacts with the Stock Order Menu, which displays four primary tabs: Warehouse, Sales Retail, Service Orders, and Work Orders.
2. Selection: Clicking on a specific tab highlights that tab as "active" and immediately directs the user to the corresponding list view for that category.
3. Viewing Data: Once on a specific list page (e.g., Warehouse Stock Orders), the user can view existing records in a table format.
4. Initiating Action: On the Warehouse view, the user can click the "+ New Stock Order" button to open a data entry window.
5. Submission: Within the new order window, the user fills out the required information (such as order type and warehouse location). The system validates the input to ensure all fields are complete before saving the new order and closing the window.

1.3 Key Concepts

- Tabbed Navigation: A user interface design that allows users to switch between different views or categories without leaving the main page, keeping the workspace organized.
- List View: A dedicated page that displays a collection of records, allowing users to monitor and manage their stock orders in one place.
- Primary Action Button: A prominent button (e.g., "+ New Stock Order") designed to help users quickly perform the most important task on a specific page.
- Form Validation: A safety feature that checks if all required information has been entered correctly before allowing the user to submit a new record, preventing incomplete or erroneous data.

1.4 Business Value

This feature streamlines inventory management by reducing the time users spend searching for specific order types. By grouping related tasks into a single, intuitive menu, the system minimizes navigation complexity and improves user productivity. Furthermore, the standardized creation process ensures that all new stock orders are

captured with the necessary information, leading to better data accuracy and more reliable inventory tracking across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Return Fixed Assets Tab

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Purchase Return feature has been updated to include a dedicated tab for managing Fixed Asset returns. This enhancement allows users to toggle between standard inventory returns and fixed asset returns within a single, unified interface, ensuring that the correct data and forms are displayed based on the type of return being processed.

1.2 Step-by-Step Flow

1. The user navigates to the Purchase Return section of the Lumi ERP.
2. The system displays a navigation bar containing two tabs: "Standard" and "Fixed Asset," along with a "New Purchase Return" button.
3. If the user selects the "Standard" tab, the system displays the standard purchase return list or form.
4. If the user selects the "Fixed Asset" tab, the system switches the view to the dedicated Fixed Asset purchase return page.
5. The user can initiate a new return at any time by clicking the "New Purchase Return" button, regardless of which tab is currently active.

1.3 Key Concepts

- Standard Purchase Return: The default process for returning general inventory items to a supplier.
- Fixed Asset Purchase Return: A specialized process for returning high-value, long-term assets (such as machinery or equipment) that require different tracking or accounting treatment than standard inventory.
- Tabbed Navigation: A user interface design that allows users to switch between different categories of information without leaving the current page.

1.4 Business Value

By separating Fixed Asset returns from Standard returns, the system improves data accuracy and operational efficiency. Users no longer need to navigate to different areas of the software to manage these distinct processes. This clear separation ensures that the specific accounting and tracking requirements for fixed assets are handled correctly, reducing the risk of errors in inventory and asset management reporting.

BUSINESS REQUIREMENTS DOCUMENT

Company - Stock Outgoings Search and Filter Bar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Outgoing Search and Filter Bar is a tool designed to help users quickly locate specific outgoing stock records within the Lumi ERP system. By providing a set of intuitive controls, users can narrow down long lists of records based on document references, status, origin, business entity, or creation date.

1.2 Step-by-Step Flow

1. Input Criteria: The user interacts with one or more of the available filter fields (Reference Code, Status, Source, Entity, or Date Range).
2. Refinement: The system tracks these selections in the background. If a user leaves a field empty, the system ignores that specific filter entirely.
3. Trigger Search: Once the user clicks the "Search" button, the system gathers all active (non-empty) filter criteria.
4. Data Retrieval: The system sends a request to the database using only the active filters.
5. Display Results: The outgoing stock list is updated to show only the records that match the selected criteria, automatically resetting the view to the first page of results.

1.3 Key Concepts

- Reference Code: A text-based search that finds documents starting with the specific characters entered by the user.
- Workflow State: A status filter that allows users to view records by their current progress (e.g., Draft, Confirmed, Approved, or Cancelled).
- Source: A combined filter that identifies the origin of the stock, whether it is a specific store or a warehouse.
- Entity: A filter that isolates records associated with a specific business unit or branch within the company.
- Date Range: Two date pickers that define a "start" and "end" window, allowing users to find records created within a specific timeframe.
- Dynamic Filtering: The system’s ability to ignore empty fields, ensuring that the search results are only restricted by the criteria the user actually provides.

1.4 Business Value

This feature significantly improves operational efficiency by reducing the time spent manually scrolling through stock records. By allowing users to filter by specific business attributes—such as the source location or the status of a document—staff can perform audits, track outgoing shipments, and resolve inventory discrepancies much faster. The flexible, "ignore-if-empty" design ensures that users have full control over the level of detail in their search without being forced to fill out unnecessary fields.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Workflow Internal Status Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Workflow component is a visual progress tracker designed to provide immediate clarity on the current stage of a purchase order. By displaying the order's journey horizontally, users can quickly identify where an order stands in the fulfillment process, from its initial creation to final receipt.

1.2 Step-by-Step Flow

The component tracks the order through four distinct stages:

1. Draft: The order is being created.
2. Store Confirmed: The store has verified the order details.
3. Warehouse Sent: The warehouse has processed and dispatched the items.
4. Store Received: The store has successfully received the shipment.

As an order moves through these stages, the component updates automatically:

* Passed Stages: Any stage already completed is marked with a green checkmark, indicating it is finished.

* Active Stage: The current stage is highlighted in blue, showing exactly where the order is right now.

* Pending Stages: Any future stages that have not yet been reached remain in a neutral, uncolored state.

1.3 Key Concepts

- Workflow Tracker: A visual progress bar that shows the sequence of steps required to complete a purchase order.
- Status Indicators: Visual cues (colors and icons) that distinguish between completed, current, and upcoming tasks.
- Chevron Separators: Small arrow icons placed between steps to visually guide the user through the chronological flow of the process.

1.4 Business Value

This feature eliminates guesswork for staff by providing a "single source of truth" for order status. By offering a clear, at-a-glance view of the fulfillment lifecycle, it reduces the need for manual status inquiries, helps teams identify bottlenecks in the supply chain, and ensures that both store and warehouse personnel are aligned on the progress of every purchase order.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Stock Return Warehouse Form Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Stock Return Warehouse Form" is a user interface component designed to help staff record the return of inventory items. It provides a structured way to document where stock is coming from, where it is being sent, and any relevant reference information. The system automatically handles document tracking, ensuring that each return is logged accurately within the Lumi ERP system.

1.2 Step-by-Step Flow

1. Document Identification: The system automatically generates a unique Document Number for the return. This field is read-only and cannot be modified by the user.
2. Source Selection: The user selects the originating store using a searchable dropdown menu. This field is mandatory.
3. Destination Selection: The user selects the destination warehouse and the internal supplier from two separate dropdown menus. Both fields are mandatory.
4. Additional Details: The user may optionally enter a reference code and any additional notes regarding the return.
5. Validation: As the user fills out the form, the system immediately checks that all required fields are completed.
6. Submission: Once the user clicks the submit button, the system performs a final check and sends the completed information to the inventory database to finalize the stock return.

1.3 Key Concepts

- Searchable Dropdown: A selection tool that allows users to type a name to quickly filter and find a specific store from a long list.
- Required Fields: Specific pieces of information (Store, Warehouse, and Supplier) that must be provided before the system will allow the return to be processed.
- Read-only Field: A display-only area that shows system-generated information (like the Document Number) that the user cannot change.
- Validation: An automated process that ensures the form is complete and accurate before it is saved, preventing errors in inventory records.

1.4 Business Value

- Data Accuracy: By requiring specific fields and using dropdown menus for locations and suppliers, the system reduces manual entry errors and ensures consistent data across the inventory system.

- Efficiency: The searchable interface and auto-generated document numbers speed up the administrative process for warehouse staff.
- Auditability: Every return is captured with a unique reference, making it easier for management to track stock movement and reconcile inventory levels between stores and warehouses.

2. Logic

2.1 Overview

The "New Stock Return Warehouse Form" is a feature designed to help staff manage the movement of inventory back into the system. It provides a structured way to record where stock is coming from, where it is being returned to, and any relevant tracking information. This ensures that inventory records remain accurate and that every return is properly documented for auditing purposes.

2.2 Step-by-Step Flow

1. Select Origin: The user selects the store from which the stock is being returned using a searchable list.
2. Select Destination: The user chooses where the stock is going. They must select either a specific warehouse or an internal supplier. The system is designed to ensure only one of these destinations is active at a time.
3. Enter Reference Details: The user provides a unique reference code for the transaction to help with future tracking.
4. Add Optional Notes: The user can include any additional context or comments regarding the return.
5. Validation: Before submission, the system checks that a store and reference code have been provided, and that a valid destination (warehouse or supplier) has been selected.
6. Submission: Once validated, the system saves the return record and confirms the transaction with a unique ID and timestamp.

2.3 Key Concepts

- Stock Return: The process of moving inventory from a retail store back into a central warehouse or returning it to an internal supplier.
- Reference Code: A unique identifier (such as a tracking number or invoice ID) used to easily locate and identify the return transaction later.
- Validation: A safety check performed by the system to ensure all mandatory information is provided before the data is saved, preventing incomplete or incorrect records.
- Destination Logic: A smart form feature that ensures the user cannot accidentally send stock to both a warehouse and a supplier simultaneously; selecting one automatically clears the other.

2.4 Business Value

- Inventory Accuracy: By standardizing how returns are recorded, the business maintains a real-time, accurate view of stock levels across all locations.
- Operational Efficiency: The searchable dropdowns and clear validation rules reduce manual data entry errors and speed up the process for staff.
- Audit Readiness: Every return is captured with a reference code and timestamp, creating a clear paper trail that simplifies inventory audits and troubleshooting.

3. Data

3.1 Overview

The "New Stock Return Warehouse Form" is a feature within the Lumi ERP system designed to help staff accurately record the movement of inventory when it is being returned. This form allows users to specify where the stock is coming from and where it is being sent, ensuring that inventory records remain accurate and traceable.

3.2 Step-by-Step Flow

1. Select Origin: The user selects the store from which the stock is being returned using a searchable dropdown list.
2. Select Destination: The user chooses the destination for the returned stock. They must select either a specific warehouse or an internal supplier to complete the transaction.
3. Add Details: The user enters a reference code (such as a tracking or invoice number) and any additional notes regarding the return.
4. Validation: The system checks that a valid destination (either a warehouse or an internal supplier) has been selected.
5. Submission: Once all required information is provided, the system saves the return record, updating the inventory logs accordingly.

3.3 Key Concepts

- Store: The physical or digital location where the returned stock originated.
- Warehouse: A primary destination option for returned items, used for centralized storage.
- Internal Supplier: An alternative destination option representing internal departments or entities that handle returned goods.
-

Reference Code: A unique identifier or tracking number used to link the return to specific paperwork or previous transactions.

- Validation: A safety check performed by the system to ensure that a return cannot be processed without a clearly defined destination.

3.4 Business Value

This feature streamlines the inventory management process by providing a standardized way to track stock returns. By requiring a clear origin and destination, the system reduces the risk of "lost" inventory and provides an audit trail for all returned items. This improves overall stock accuracy and helps management maintain better visibility into how goods move throughout the organization.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Stock Return Warehouse Table Columns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Return Table is a new interface component designed to help staff manage product returns and claims efficiently. It provides a structured, row-based layout where users can search for products, specify quantities, categorize the transaction, and provide reasons for the return. The table is dynamic, allowing users to add or remove items as needed, and includes built-in safeguards to ensure data accuracy.

1.2 Step-by-Step Flow

1. Initiate Entry: Users start with a blank row or click the "Add Product" button to create a new entry in the table.
2. Search Product: Users type at least three characters into the product search field. The system suggests matching products; selecting one automatically populates the current store quantity.
3. Define Return Details: For each row, the user enters the quantity to be returned. The system validates this input to ensure the return amount does not exceed the current store stock.
4. Categorize and Explain: The user selects the transaction type ("Return" or "Claim") and enters a mandatory reason for the action.
5. Manage Rows: Users can remove any row using the "X" button if an item was added by mistake.
6. Bulk Processing: For larger requests, users can utilize the "Upload Manager" button to process multiple items at once.

1.3 Key Concepts

- Return vs. Claim: A classification system that helps the business distinguish between standard inventory returns and specific damage or warranty claims.
- Store Quantity: The current stock level retrieved automatically from the system, which serves as a ceiling for the return quantity to prevent data entry errors.
- Dynamic Row Management: The ability to add or remove rows on the fly, providing flexibility for returns that involve multiple different products.
- Validation: An automated check that prevents users from submitting a return quantity that is higher than what is currently available in the store.

1.4 Business Value

- Data Accuracy: By automatically pulling store quantities and validating return amounts, the system reduces human error and prevents invalid inventory adjustments.
-

Operational Efficiency: The intuitive row-based design and bulk upload capability allow staff to process complex returns faster than manual entry methods.

- Improved Reporting: Standardizing the "Reason" and "Type" fields ensures that the business can accurately track why inventory is being returned, helping to identify trends in product quality or store issues.

2. Logic

2.1 Overview

The new Stock Return Warehouse table feature streamlines the process of returning items to inventory. It allows users to quickly search for products, automatically pulls in current stock levels, and ensures that all necessary information—such as the reason for the return and the quantity—is captured and validated before the return is processed.

2.2 Step-by-Step Flow

1. Product Search: As you type at least three characters into the product search field, the system searches by SKU, product code, or name to find the correct item.
2. Auto-Fill: Once you select a product from the search results, the system automatically populates the "Store Quantity" field with the current stock level and saves the product identifier for the record.
3. Data Entry: You then complete the row by entering the quantity to be returned, selecting the type of transaction (Return or Claim), and providing a reason for the action.
4. Validation: Before the entry is finalized, the system checks that a product is selected, the return quantity is greater than zero, a transaction type is chosen, and a reason is provided. If any information is missing or incorrect, the system will alert you to fix it.

2.3 Key Concepts

- Product Search: A smart lookup tool that helps you find items quickly using common identifiers like names or codes.
- Store Quantity: The current amount of stock available, which is automatically retrieved to provide context for the return.
- Transaction Type: A classification for the entry, specifically distinguishing between a standard "Return" and a "Claim."
- Validation: An automated check that ensures all required fields are filled out correctly to prevent errors in inventory records.

2.4 Business Value

This feature reduces manual data entry and minimizes human error by automating the retrieval of stock levels and validating inputs in real-time. By standardizing how returns and claims are recorded, the system ensures inventory data remains accurate and reliable, ultimately saving time for warehouse staff and providing better visibility into why stock is being returned.

3. Data

3.1 Overview

The new Stock Return Warehouse table is designed to streamline the process of logging returned inventory. This feature provides a structured interface where staff can easily select products being returned, view their current stock levels, and document the specific details of the return, such as the quantity and the reason for the return.

3.2 Step-by-Step Flow

1. Search for Product: The user begins by searching for a product using its name, SKU, or code. The system requires at least three characters to begin the search.
2. Select Product: Once the correct product is selected from the search results, the system automatically adds a new row to the table.
3. Auto-Populate Data: The system instantly fills in the "Store Qty" field with the current stock level for that specific product, ensuring the user has accurate reference data.
4. Input Return Details: The user enters the quantity being returned and selects the return type (e.g., Damaged, Expired, or Overstock) from a dropdown menu.
5. Add Reason: The user provides any additional context or notes regarding the return in the "Reason" field.

3.3 Key Concepts

- Product Search: A smart lookup tool that filters the product catalog based on partial matches to ensure the correct item is selected quickly.
- Store Qty: A read-only field that displays the current inventory count, providing immediate visibility into stock levels at the time of the return.
- Return Type: A standardized category selection that helps the business track why items are being returned, which is essential for inventory reporting.
- Return Qty: The specific amount of stock being processed back into the system.

3.4 Business Value

This feature improves inventory accuracy by reducing manual data entry errors. By automatically pulling in current stock levels and providing standardized categories for returns, the system ensures that inventory records remain

consistent and reliable. This allows warehouse managers to better track product loss, identify trends in damaged or expired goods, and maintain a clearer picture of actual stock availability.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Stock Opname Form Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The New Stock Opname Form Card is a dedicated interface designed to help inventory managers record stock counts efficiently. This form allows users to specify the location, product categories, and brands being audited, while providing tools to quickly populate product lists to save time during the data entry process.

1.2 Step-by-Step Flow

1. Select Store: The user begins by selecting the relevant store from a dropdown menu. This selection is mandatory and acts as the foundation for the rest of the form.
2. Define Scope: The user selects the specific Product Type and Product Brand they wish to audit.
3. Set Date and Notes: The user enters the completion date for the audit and adds any necessary context in the required notes field.
4. Reference Code: A unique reference code is automatically generated by the system once the form is created; this field is read-only and cannot be manually edited.
5. Populate Data: The user can click the "Autofill" button to automatically pull in the relevant product list for the selected store. If the store has not been selected, the system will prompt the user to do so first.
6. Advanced Options: For more complex requirements, the user can click the "Advanced" button to open a modal with additional configuration options.
7. Submission: Once all required fields are filled, the user submits the form to save the stock opname record. The system validates the input and alerts the user if any required information is missing.

1.3 Key Concepts

- Stock Opname: The process of verifying the physical inventory count against the system records.
- Autofill: A time-saving feature that automatically populates the form with a list of products based on the selected store, reducing manual data entry.
- Reference Code: A unique identifier assigned to each stock audit record for tracking and reporting purposes.
- Validation: A built-in check that ensures all mandatory fields (Store, Product Type, Product Brand, Date, and Notes) are completed before the record can be saved.

1.4 Business Value

- Increased Accuracy: By requiring specific store and product details, the form ensures that inventory data is categorized correctly, reducing errors in stock reporting.
-

Operational Efficiency: The "Autofill" functionality significantly reduces the time spent manually adding products to an audit, allowing staff to focus on the physical count.

- Standardized Record Keeping: The mandatory fields and automated reference codes ensure that every stock audit is documented consistently, making it easier to track inventory history and audit trails across different store locations.

2. Logic

2.1 Overview

The "New Stock Opname Form Card" is a feature designed to help staff initiate a new inventory count session. By selecting specific criteria—such as the store location, product category, and brand—users can create a structured "draft" session. This ensures that the stock-taking process is organized and targeted, allowing for accurate tracking of inventory levels within the Lumi ERP system.

2.2 Step-by-Step Flow

1. Selection: The user selects the specific store, product type, and product brand from the provided dropdown menus on the form card.
2. Validation: The system checks that all three fields have been filled out. If any information is missing, the system will prompt the user to complete the selection.
3. Initialization: Once the criteria are confirmed, the system records the current date and time to create a new inventory session.
4. Session Creation: The system saves this new session as a "Draft" in the database, establishing the foundation for the upcoming stock count.

2.3 Key Concepts

- Stock Opname: The formal process of counting physical inventory to ensure it matches the records in the system.
- Draft Status: A temporary state for a new inventory session, indicating that the count has been initialized but is not yet finalized or submitted.
- Filter Criteria: The specific parameters (Store, Product Type, and Brand) used to narrow down the scope of the inventory count, ensuring staff only count the items relevant to their current task.

2.4 Business Value

This feature streamlines the inventory management process by reducing manual errors and providing a clear starting point for stock-taking. By requiring users to define the scope of the count (store, type, and brand) before

they begin, the business ensures that inventory data remains organized, traceable, and consistent across all locations. This leads to more reliable stock reports and better-informed purchasing decisions.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Stock Opname Product Form Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Opname Product Form is a user-friendly interface designed to help staff record physical inventory counts. It provides a flexible table where users can manually enter product details and their corresponding counted quantities. The feature also includes tools to manage the list efficiently, such as bulk uploading via files or printing blank forms for manual tallying on the warehouse floor.

1.2 Step-by-Step Flow

1. Accessing the Form: Users view the "Products" section, which displays a table for entering inventory data.
2. Managing the List:

- Users can add new rows to the table as needed to accommodate different products.
- Users can remove any row from the list by clicking the delete button.
- Users can utilize the "Upload Manager" to import product lists or the "Print Blank Form" button to generate physical sheets for manual counting.

3. Data Entry: For each row, the user inputs the product identifier (SKU, code, or name) and the counted quantity.
4. Validation: The system automatically checks that the entered quantity is a valid, non-negative number. If an invalid number is entered, the system highlights the field to alert the user.
5. Submission: Once the list is complete, the system processes the entries and saves the counted stock data to the inventory records.

1.3 Key Concepts

- Stock Opname: The process of physically counting and verifying the actual stock levels currently held in the warehouse.
- Product Identifier: A unique reference (such as a SKU, product code, or name) used to ensure the correct item is being recorded.
- Counted Quantity: The actual number of items found during the physical stock check.
- Validation: A built-in safety check that prevents errors by ensuring only logical, positive numbers are accepted for stock counts.

1.4 Business Value

- Accuracy: By providing real-time validation, the system reduces human error during data entry, ensuring that inventory records match physical reality.
-

Efficiency: The ability to upload files and print blank forms streamlines the workflow, saving time for warehouse staff during busy stock-taking periods.

- Flexibility: The dynamic row system allows users to scale the form to fit any size of inventory count, whether it is a small spot-check or a full warehouse audit.

2. Logic

2.1 Overview

The New Stock Opname Product Form Card is a feature designed to help staff accurately record physical inventory counts within the Lumi ERP system. This tool allows users to select a specific product and input the quantity they have physically counted, ensuring that the system's digital records match the actual stock on hand.

2.2 Step-by-Step Flow

1. Data Entry: The user selects a product and enters the quantity they have physically counted.
2. Validation: The system checks the input to ensure a valid product is selected and that the quantity entered is a positive number.
3. Mapping: The system organizes the information into the required format for the inventory database.
4. Submission: The system sends the data to the inventory records.
5. Confirmation: The system confirms that the stock count has been successfully recorded or alerts the user if there was an issue with the submission.

2.3 Key Concepts

- Stock Opname: The process of physically counting inventory items to verify that the actual stock matches the records in the system.
- Product ID: A unique identifier used to ensure the correct item is being updated in the inventory database.
- Counted Quantity: The specific number of items physically found during the stock check.
- Validation: A safety check performed by the system to prevent errors, such as entering negative numbers or missing product information, before the data is saved.

2.4 Business Value

This feature streamlines the inventory reconciliation process by providing a simple, error-resistant interface for staff. By ensuring that physical counts are accurately captured and validated before they reach the database, the business can maintain high inventory accuracy, reduce discrepancies, and make better-informed purchasing and sales decisions.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Returns - Return Details Workflow Status Bar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Return workflow bar is a visual navigation and control component located on the inventory page. It provides users with a clear, at-a-glance view of where a specific return document stands in the approval process, while offering quick access to essential document management actions.

1.2 Step-by-Step Flow

1. Status Visualization: The bar displays the document's journey through four distinct stages: DRAFT, CONFIRMED, SENT, and APPROVED.
2. Progress Tracking: As a document moves through the workflow, the bar highlights the current stage with solid styling, marks previous stages as completed, and keeps future stages in a muted, pending state.
3. Document Management: Users can interact with the action buttons located on the right side of the bar to manage the document:

* Print: Opens the system print dialog to generate a physical or digital copy.

* Send: Advances the document to the next stage in the workflow.

* Cancel: Discards any unsaved changes and reverts the document to its previous state after a confirmation prompt.

1.3 Key Concepts

- Workflow Stages: The sequential steps (Draft, Confirmed, Sent, Approved) that a purchase return must pass through.
- Status Pill: A visual indicator representing a single stage; its appearance changes based on whether the stage is active, completed, or pending.
- Chevron Icon: A graphical separator used between stages to indicate the forward direction of the workflow.
- Action Buttons: A set of controls that allow users to perform immediate tasks like printing, advancing the workflow, or canceling changes without leaving the status bar area.

1.4 Business Value

This feature improves operational efficiency by providing immediate visibility into the status of franchise returns, reducing the need for users to search for document updates. By centralizing status tracking and common actions (Print, Send, Cancel) into a single, consistent interface, it minimizes user error, ensures a standardized process for handling returns, and allows staff to manage inventory documentation with greater speed and confidence.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Returns - Return Internal Details Detail Panel

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Return Detail Panel is a dedicated view within the Lumi ERP system that provides a comprehensive summary of a specific purchase return. It acts as a "digital file" for a return transaction, allowing users to quickly review all relevant administrative, logistical, and status-related information in one organized location.

1.2 Step-by-Step Flow

1. Data Retrieval: When a user selects a specific purchase return, the system automatically fetches the relevant details from the database.
2. Loading State: While the information is being retrieved, the system manages the process to ensure a smooth user experience.
3. Displaying Left-Column Details: Once loaded, the panel displays core identification and logistical data, including document and reference numbers, the originating store, the destination supplier and warehouse, user audit trails (who created/updated the record), and any associated notes.
4. Displaying Right-Column Details: The panel simultaneously displays status-based timestamps and financial references, including creation and update dates, approval and dispatch dates, and the associated accounting journal reference.
5. Handling Empty Data: If a specific field (such as an approval date or a note) has not yet been populated, the system displays a placeholder (a dash) to keep the interface clean and readable.

1.3 Key Concepts

- Purchase Return: A formal record of inventory being sent back from a franchise store to a supplier.
- Detail Panel: A structured layout that organizes complex transaction data into two clear columns for easy reading.
- Audit Trail: Information showing who created or modified a record and when, ensuring accountability and transparency.
- Status-Driven Fields: Specific data points, such as "Approve Date" or "Sent Date," that remain blank until the return reaches those specific stages in its lifecycle.
- Journal Reference: A link to the accounting entry associated with the return, ensuring the inventory movement is correctly recorded in the financial system.

1.4 Business Value

This feature improves operational efficiency by centralizing all critical information regarding a purchase return. By providing a clear, at-a-glance view of the return's status, history, and logistical details, staff can quickly

verify the progress of a return, resolve discrepancies faster, and maintain accurate records without needing to cross-reference multiple documents or systems.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal Details Panel

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Internal Details panel is a read-only information display designed to provide a comprehensive view of a specific purchase order. It acts as a centralized "fact sheet," allowing staff to quickly verify the origin, destination, timeline, and administrative history of an order without needing to edit or modify the data.

1.2 Step-by-Step Flow

1. Document Identification: The panel displays the unique Document Number and any associated Reference Number to help users identify the specific order.
2. Logistics Details: The system shows the source (Warehouse and Supplier) and the final destination (Deliver To) to clarify the movement of goods.
3. Timeline Tracking: The panel lists critical dates, including when the order was created, updated, sent, received, and when payment or fulfillment is due.
4. Audit and Administrative Data: The system displays who created or updated the record, the associated journal entry, and any additional notes provided for the order.

1.3 Key Concepts

- Read-Only Display: Information is presented for viewing purposes only; users cannot change these values directly within this panel.
- Audit Trail: A collection of timestamps and user identifiers that provide transparency regarding who managed the order and when actions were taken.
- Logistics Mapping: A clear breakdown of the supply chain path, showing exactly where an order originated and where it is intended to be delivered.

1.4 Business Value

This feature improves operational efficiency by providing a "single source of truth" for franchise purchase orders. By consolidating logistical, historical, and administrative data into one view, staff can resolve inquiries faster, reduce the need to search through multiple screens or documents, and maintain better oversight of the procurement lifecycle.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Details Tab Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Details page is designed to provide a centralized view for managing individual purchase orders. To help users navigate efficiently, we have implemented a tabbed navigation system at the top of the page. This allows users to quickly switch between the core order information, associated invoices, and any return records without leaving the context of the specific purchase order they are viewing.

1.2 Step-by-Step Flow

1. Accessing the Order: When a user opens a specific purchase order, the system loads the "Details" view by default.
2. Navigation Bar: A navigation menu appears at the top of the screen, displaying three distinct tabs: Details, Invoice, and Returns.
3. Visual Feedback: The system automatically highlights the tab corresponding to the page the user is currently viewing, ensuring they always know their location within the order record.
4. Switching Views: Users can click on any of the three tabs to instantly navigate to that specific section of the purchase order.
5. Data Loading: As the user switches tabs, the system fetches and displays the relevant information (such as order status, total amounts, or franchise-specific details) for that section.

1.3 Key Concepts

- Tabbed Navigation: A user interface pattern that organizes related information into separate, selectable sections, reducing clutter on the screen.
- Active State: A visual indicator (such as an underline or color change) that shows the user which tab is currently selected.
- Purchase Order Details: The primary view containing essential data points, such as the franchise ID, the current status of the order, and the total financial amount.

1.4 Business Value

- Improved Efficiency: By grouping related information (Details, Invoices, Returns) into a single view, users spend less time searching for documents and more time managing orders.
- Enhanced User Experience: The intuitive tabbed layout provides a consistent and predictable way to navigate complex order records, reducing the learning curve for new staff.
- Data Clarity: Centralizing key metrics like order status and total amounts ensures that stakeholders have immediate access to the most critical information needed for decision-making.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal Details Table

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Details Table is a component designed to provide a clear, itemized view of inventory orders within the Lumi ERP system. It allows users to track the lifecycle of a purchase order—from the initial request to the final receipt—while providing automated calculations to ensure accuracy across all line items.

1.2 Step-by-Step Flow

1. Data Loading: The system receives a list of purchase order items associated with a specific franchise order.
2. Itemized Display: Each item is rendered as a row in the table, displaying key details such as the SKU, product name, product code, quantities (ordered, sent, and received), pricing, and any relevant remarks from the store or warehouse.
3. Automated Calculation: As the table loads, the system automatically aggregates the values for all quantity and amount columns across every row.
4. Summary Presentation: A dedicated footer row displays these calculated totals, providing an immediate snapshot of the entire order's status and financial impact.

1.3 Key Concepts

- Line Item Tracking: A detailed breakdown of individual products within an order, including specific identifiers like SKU and product codes.
- Lifecycle Quantities: Columns that track the progression of stock, specifically showing what was ordered, what has been dispatched (sent), and what has been successfully received.
- Financial Aggregation: The automatic summing of order amounts, sent amounts, and received amounts to provide a high-level financial overview of the purchase order.
- Operational Remarks: Dedicated fields for both store and warehouse staff to communicate notes or updates regarding specific items.

1.4 Business Value

- Improved Accuracy: By automating the calculation of totals, the system eliminates the risk of manual arithmetic errors, ensuring that financial reporting and inventory counts are always precise.
- Enhanced Visibility: The table provides a single source of truth for both store and warehouse teams, allowing them to see exactly where an order stands in the fulfillment process.
- Operational Efficiency: With all necessary data—including remarks and financial totals—presented in one view, staff can quickly identify discrepancies between ordered, sent, and received quantities, leading to faster resolution of inventory issues.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Order Details Search and Filter Bar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Search and Filter Bar is a new utility component designed to help users quickly locate specific items within the Lumi ERP inventory. Located at the top of the inventory page, this toolbar provides a streamlined way to narrow down large product lists by searching for specific identifiers or names, while also offering a convenient way to export the resulting data.

1.2 Step-by-Step Flow

1. Input Data: The user enters a Stock Keeping Unit (SKU) into the SKU field or a product name into the Product Name field.
2. Real-time Validation: As the user types, the system immediately checks the input to ensure it meets formatting rules (e.g., preventing invalid characters). If the input is invalid, the system will not accept the entry.
3. Submit Search: Once the desired criteria are entered, the user clicks the Search button (marked with a magnifying glass icon) to refresh the inventory list based on the filters.
4. Export Results: After the list has been filtered, the user can select the Export button to access options for downloading or sharing the current view of the inventory.

1.3 Key Concepts

- SKU Filtering: A search method using the unique alphanumeric code assigned to a product.
- Product Name Filtering: A search method using the descriptive name of the product.
- Input Validation: A built-in safety feature that ensures data quality by blocking special characters or overly long entries before a search is even performed.
- Export Functionality: A tool that allows users to take the filtered list of inventory and move it into an external format for reporting or record-keeping.

1.4 Business Value

This feature significantly improves operational efficiency by reducing the time staff spend manually scrolling through inventory. By providing immediate feedback during data entry, it prevents search errors and ensures that users get accurate results quickly. Furthermore, the integrated export capability bridges the gap between the digital inventory system and external reporting needs, supporting better decision-making and stock management.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Order Details Details Panel

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Order Details Panel is a read-only information display designed to provide a comprehensive snapshot of a specific stock order. It organizes critical tracking, logistical, and administrative data into a clean, two-column layout, allowing users to quickly review the status and history of an order without the risk of accidental modification.

1.2 Step-by-Step Flow

1. Selection: The system retrieves the specific data for the selected stock order.
2. Left Column Display: The panel populates the left side with core identification and logistical details, including reference codes, warehouse locations (source and destination), user accountability (who created or updated the record), and any attached notes.
3. Right Column Display: The panel populates the right side with chronological and system-related data, including timestamps for creation, updates, and key lifecycle milestones (confirmed, sent, and received dates).
4. Formatting: The system automatically formats all date fields into a readable standard format.
5. Empty State Handling: If a specific piece of information (such as a "Received Date") is not yet available, the system displays a dash (—) to indicate the field is empty rather than showing an error or blank space.

1.3 Key Concepts

- Read-Only View: A display-only interface that ensures data integrity by preventing users from editing information directly within this panel.
- Lifecycle Milestones: Key dates in the order process (Confirmed, Sent, Received) that track the progress of the stock movement.
- Data Mapping: The process of pulling specific information from the system database and placing it into clearly labeled fields for the user.
- Placeholder Logic: A standard way of handling missing data, ensuring the interface remains clean and professional even when certain fields are not yet applicable.

1.4 Business Value

This feature improves operational efficiency by providing staff with a "single source of truth" for any given stock order. By centralizing administrative, logistical, and timeline data in one view, it reduces the time spent searching through multiple screens or reports. The read-only design provides peace of mind, ensuring that critical order history and tracking information remain secure and accurate during the review process.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Order Details Workflow Status Bar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Order Workflow Bar is a visual component designed to help users track the progress of a stock order. It provides a clear, at-a-glance view of where an order sits within its lifecycle—from initial creation to final receipt—while offering quick-access controls to manage the order directly from the inventory page.

1.2 Step-by-Step Flow

1. Status Visualization: The bar displays four distinct stages: "DRAFT," "SENT," "WAREHOUSE SENT," and "STORE RECEIVED." The current stage of the order is highlighted to distinguish it from pending or completed steps.
2. Action Selection: Users can interact with the order using three primary buttons located on the right side of the bar:

* Print: Opens the system print dialog to generate a physical or digital copy of the order.

* Confirm: Advances the order to the next stage in the workflow.

* Cancel: Discards the current order.

3. Confirmation & Processing:

* If "Confirm" is selected, the system updates the order status immediately.

* If "Cancel" is selected, the system triggers a prompt asking the user to verify their choice before finalizing the cancellation to prevent accidental data loss.

1.3 Key Concepts

- Workflow Stages: The sequential milestones an order must pass through, represented as a visual progression bar.
- Active vs. Pending: A visual distinction where the current stage is highlighted (active) and future stages are shown as upcoming (pending).
- State Transition: The process of moving an order from one stage to the next (e.g., moving from Draft to Sent) via the Confirm action.
- Action Controls: Dedicated buttons that allow users to perform common administrative tasks without leaving the current screen.

1.4 Business Value

-

Improved Visibility: By clearly displaying the status of an order, team members can instantly identify bottlenecks or verify the progress of inventory movements without searching through logs.

- Operational Efficiency: Centralizing key actions (Print, Confirm, Cancel) directly on the status bar reduces the number of clicks required to manage orders, saving time for warehouse and store staff.
- Error Reduction: The inclusion of a confirmation prompt for cancellations acts as a safeguard, preventing accidental deletion of active stock orders and ensuring data integrity.

2. Logic

2.1 Overview

The Stock Order Workflow Status Bar is a visual component designed to help you manage the lifecycle of your inventory orders. It provides a clear way to move an order forward by confirming it or to stop the process by cancelling it. This feature ensures that the system accurately tracks the current state of every order, providing immediate feedback whenever a status change occurs.

2.2 Step-by-Step Flow

1. Validation: When you click a button to change an order's status, the system first verifies that the specific order exists in the database.
2. Status Update:

- If you choose to Confirm, the system updates the order status to "Confirmed," marking it as ready for the next stage of the workflow.
- If you choose to Cancel, the system updates the order status to "Cancelled," effectively stopping the workflow.

3. Timestamping: The system automatically records the exact time the change was made, ensuring an accurate audit trail for your inventory records.
4. Confirmation: The system sends back a success message and the updated order details, allowing the status bar to refresh and display the new current state to the user.

2.3 Key Concepts

- Workflow Status: The current stage of an order (e.g., Confirmed or Cancelled), which dictates what actions can be taken next.
- Status Transition: The process of moving an order from one state to another, triggered by user interaction.
- Audit Timestamp: A system-generated record of when a change occurred, which is essential for tracking inventory history.
-

Validation: A safety check performed by the system to ensure that an order is valid and available before any changes are applied.

2.4 Business Value

This feature brings clarity and control to your inventory management process. By providing a dedicated status bar, your team can see at a glance exactly where an order stands in the workflow. This reduces manual tracking errors, ensures that inventory records remain accurate, and provides a reliable, consistent way to handle order confirmations and cancellations across the organization.

3. Data

3.1 Overview

The Stock Order Status Bar is a visual component designed to help you manage the lifecycle of your inventory orders. It provides a clear way to move an order forward to its next stage or cancel it if necessary. This feature ensures that your order records remain accurate and that you are always aware of the current progress of your stock requests.

3.2 Step-by-Step Flow

1. Initiating an Action: You interact with the status bar by clicking either the "Confirm" or "Cancel" button depending on the desired outcome for the order.
2. Confirmation (for Cancellations): If you choose to cancel, the system will prompt you to confirm your decision to ensure no orders are discarded by mistake.
3. Processing the Request: The system sends your request to the inventory database to update the order status.
4. Updating the View: Once the system processes the change, the status bar automatically refreshes to reflect the new state of the order.
5. Feedback: If you confirm an order, the system will notify you that the update was successful. If an error occurs, the system will provide a message explaining the issue so you can take appropriate action.

3.3 Key Concepts

- Workflow Status: The current stage of an order (e.g., pending, confirmed, or cancelled), which dictates what actions can be taken next.
- State Transition: The process of moving an order from one stage to another, such as finalizing a draft or stopping an order in progress.
- Data Integrity: The system's way of ensuring that when you cancel an order, it reverts to its last saved, accurate state, preventing incomplete or corrupted data.

3.4 Business Value

- Operational Efficiency: By providing clear "Confirm" and "Cancel" actions directly in the status bar, staff can manage inventory orders quickly without navigating through complex menus.
- Error Reduction: The built-in confirmation step for cancellations prevents accidental data loss, while automated status updates ensure that everyone on the team sees the same, up-to-date information.
- Improved Visibility: The status bar acts as a "single source of truth," allowing users to instantly understand where an order sits in the procurement or fulfillment process.

BUSINESS REQUIREMENTS DOCUMENT

Stock - New Order Warehouse Form Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "New Order Warehouse Form" is a user-friendly interface designed to help staff create new stock transfer orders within the Lumi ERP system. This form allows users to specify where stock is coming from, where it is being delivered, and when it is expected to arrive, ensuring all necessary details are captured before an order is officially recorded.

1.2 Step-by-Step Flow

1. Select Origin: The user chooses the source warehouse from a list of available locations.
2. Select Destination: The user chooses the destination store where the stock should be delivered.
3. Enter Reference: The user provides a unique reference code for the order.
4. Set Due Date: The user selects the date by which the order is expected to be completed.
5. Set Status: The user selects the current workflow state (e.g., Draft or Confirmed).
6. Add Notes: The user may optionally include any additional comments or instructions regarding the order.
7. Validation: As the user fills out the form, the system checks that all required fields are completed.
8. Submission: Once the user clicks "Create Order," the system verifies the information and saves the new transfer order to the system.

1.3 Key Concepts

- Required Fields: Specific information—such as the source warehouse, destination store, reference code, and due date—must be provided to ensure the order can be processed correctly.
- Workflow State: A status indicator that tracks the progress of an order, starting from a "Draft" phase through to completion or cancellation.
- Reference Code: A unique identifier used to track and locate specific orders within the system.
- Transfer Order: The underlying business process where stock is moved from one internal location (warehouse) to another (store).

1.4 Business Value

This feature streamlines inventory management by providing a standardized way to initiate stock transfers. By enforcing data entry requirements at the point of creation, the system reduces errors, improves tracking accuracy, and ensures that warehouse staff have clear, actionable information to fulfill delivery requests on time.

2. Logic

2.1 Overview

The New Order Warehouse Form Card is a feature within the Lumi ERP system designed to streamline the creation of stock transfer orders. It provides a user-friendly interface for staff to input essential details about moving inventory from a warehouse to a specific store. The system ensures that all critical information is captured and validated before the order is officially recorded in the database.

2.2 Step-by-Step Flow

1. Data Collection: The user fills out the form, selecting the source warehouse, the destination store, the current workflow status, a reference code, and the expected due date. An optional notes field is also available for additional context.
2. Validation: Upon submission, the system checks that all mandatory fields (source warehouse, destination store, reference code, due date, and workflow status) have been provided. If any required information is missing, the system will alert the user.
3. Mapping: The system organizes the collected information into a standardized format, automatically assigning the order type as a "Transfer" and aligning the user-selected workflow status with the internal system requirements.
4. Persistence: Once validated and mapped, the order details are securely saved to the inventory database, and the system confirms the creation of the new order.

2.3 Key Concepts

- Workflow State: The current phase of the order (e.g., Draft, Confirmed, Sent, or Received), which helps track the progress of the inventory transfer.
- Source Warehouse: The specific location from which the stock is being moved; the system only displays active warehouses to ensure accuracy.
- Reference Code: A unique identifier or tracking number assigned to the order for easy searching and auditing.
- Due Date: The target date by which the stock transfer is expected to be completed.

2.4 Business Value

This feature improves inventory management efficiency by providing a structured, error-proof way to initiate stock transfers. By enforcing mandatory fields and validating data at the point of entry, the system reduces manual errors and ensures that warehouse staff have all the necessary information to fulfill orders accurately. This leads to better visibility into stock movement and helps maintain consistent inventory levels across all store locations.

3. Data

3.1 Overview

The New Order Warehouse Form Card is a user-friendly interface component designed to help staff initiate new inventory stock orders within the Lumi ERP system. This feature streamlines the ordering process by allowing users to select a specific warehouse and define the type of order, ensuring that all new requests are captured accurately and consistently as "Draft" orders.

3.2 Step-by-Step Flow

1. Loading Available Warehouses: When the form card is opened, the system automatically retrieves a list of all currently active warehouses to ensure users only select valid locations.
2. User Selection: The user selects the desired warehouse from the provided dropdown menu and confirms the type of order (defaulting to "Restock").
3. Submission: Upon clicking the submit button, the system captures the selected warehouse and order type.
4. Order Creation: The system creates a new stock order record, automatically assigning it a "Draft" status.
5. System Refresh: Once the order is successfully created, the system automatically updates the inventory dashboard to reflect the new order, ensuring the user sees the most current information.

3.3 Key Concepts

- Active Warehouse: A facility that is currently operational and eligible to receive or process new stock orders.
- Draft Status: The initial state of a new order, indicating that it has been created but is not yet finalized or processed.
- Order Type: A classification for the request (such as "Restock"), which helps the system categorize and manage inventory movement correctly.
- Data Refresh: An automatic background process that ensures the inventory list stays up-to-date immediately after a new order is submitted.

3.4 Business Value

This feature simplifies inventory management by providing a standardized, error-proof way to initiate stock orders. By restricting selections to active warehouses and automating the initial "Draft" status, the system reduces manual data entry errors and ensures that inventory records remain organized. Furthermore, the automatic refresh functionality provides real-time visibility, allowing teams to track new orders immediately without needing to manually reload the page.

1. Frontend

1.1 Overview

The Order Warehouse Product Form Card is a dynamic interface designed to help staff create warehouse orders efficiently. It allows users to build an order list by adding multiple products, specifying quantities, recording costs, and providing necessary remarks for each item. The system ensures data accuracy by validating entries in real-time before the order is submitted for processing.

1.2 Step-by-Step Flow

1. Search for Product: Use the search dropdown to find a specific item by its SKU, code, or name. Once selected, the system links that product to the current row.
2. Enter Order Details: For each selected product, input the required quantity, the average cost, and a brief remark or note.
3. Add More Items: If the order includes multiple products, click the "Add Product" button to generate a new, empty row and repeat the process.
4. Remove Items: If a product was added by mistake, click the "Remove" (X) button on that specific row to delete it from the order.
5. Validation: As you type, the system automatically checks your entries (e.g., ensuring quantities are positive and remarks are not left blank) to prevent submission errors.
6. Submission: Once all rows are complete, the information is sent to the system, where it is automatically marked as a "pending" order for the warehouse team.

1.3 Key Concepts

- Dynamic Rows: The ability to add or remove multiple product entries within a single form, allowing for flexible order sizes.
- Real-time Validation: A built-in safety feature that checks your input as you type, providing immediate feedback if a value (like quantity or cost) is invalid.
- Pending Status: A default setting applied to all new orders, ensuring they are captured in the system for review before final processing.
- Product Search: A smart lookup tool that requires at least three characters to help you quickly locate the correct item from the inventory database.

1.4 Business Value

This feature streamlines the procurement process by replacing manual, error-prone entry with a guided, digital interface. By allowing users to group multiple products into a single order and enforcing data validation at the point of entry, the system reduces administrative overhead, minimizes order inaccuracies, and ensures that the warehouse team receives clear, actionable requests.

2. Logic

2.1 Overview

The Order Warehouse Product Form Card is a user interface component designed to streamline the process of requesting stock from the warehouse. It allows staff to select a specific product, specify the desired quantity, provide cost information, and include any necessary notes. This feature ensures that all required data is captured accurately before sending the request to the system for processing.

2.2 Step-by-Step Flow

1. Data Collection: The user fills out the form by selecting a product, entering the order quantity, providing the company's average cost for the item, and adding any relevant remarks.
2. Validation: The system checks that a valid product has been selected and that the order quantity is greater than zero. If these requirements are not met, the order cannot proceed.
3. Payload Preparation: The system organizes the collected information into a structured format, automatically assigning the order a "pending" status.
4. Submission: The completed order request is sent to the warehouse management system.
5. Confirmation: Upon successful submission, the system confirms the order creation and provides a summary of the request, including a unique identifier and the timestamp.

2.3 Key Concepts

- Warehouse Order: A formal request for stock replenishment that tracks what is being ordered, how much is needed, and the current status of the request.
- Pending Status: The default state assigned to a new order, indicating that it has been successfully submitted but has not yet been processed or fulfilled by the warehouse.
- Validation: A safety check performed by the system to ensure that essential information (like product identity and quantity) is present and correct before an order is finalized.
- Payload: The specific set of data sent from the form to the system database to ensure the order is recorded correctly.

2.4 Business Value

This feature simplifies inventory management by providing a standardized, error-resistant way to request stock. By automating the transition of order data into the system, it reduces manual entry errors, ensures that all necessary cost and remark information is captured upfront, and provides immediate visibility into pending orders, allowing for better coordination between store locations and the central warehouse.

3. Data

3.1 Overview

The Order Warehouse Product Form Card is a user-friendly interface component designed to help staff quickly replenish inventory. It allows users to select a specific product and place an order directly from the inventory management screen, ensuring that stock levels remain consistent with business needs.

3.2 Step-by-Step Flow

1. Product Identification: The system identifies the specific product you are viewing to ensure the order is linked to the correct item.
2. Quantity Entry: You enter the desired amount of the product you wish to order into the form.
3. Validation: The system checks that the quantity is a valid number greater than zero before allowing the order to proceed.
4. Submission: Once you click the "Place Order" button, the system sends the request to the warehouse to initiate the replenishment process.
5. Status Feedback: The button updates to show it is "Processing" while the request is being handled. If any issues occur during submission, an error message will appear to alert you.
6. Reset: Upon a successful order, the form clears the quantity field, readying it for the next entry.

3.3 Key Concepts

- Warehouse Product: The specific item in your inventory that is being tracked for stock levels and reordering.
- Order Quantity: The number of units you are requesting to add to your current stock.
- Pending Status: The initial state of an order once it has been submitted but before it has been fully processed by the warehouse.
- Submission State: A safety feature that prevents duplicate orders by disabling the button while the system is busy processing your request.

3.4 Business Value

This feature streamlines the inventory replenishment process by removing the need to navigate to separate screens to place orders. By integrating the ordering capability directly into the inventory view, staff can make informed, real-time decisions about stock levels, reducing the risk of stockouts and improving overall warehouse efficiency.

BUSINESS REQUIREMENTS DOCUMENT

Purchase Orders - Fixed Asset Table

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Fixed Asset Purchase Order table provides a centralized, read-only view of all purchase orders related to fixed assets. This component allows users to quickly scan the status, financial details, and progress of various asset purchases in a clean, organized list format.

1.2 Step-by-Step Flow

1. View List: The table displays a comprehensive list of all fixed asset purchase orders.
2. Identify Order: Users can locate specific orders using the Document Number or Reference Number.
3. Navigate to Details: By clicking on the Document Number, the user is redirected to a dedicated page containing full details for that specific purchase order.
4. Review Financials & Dates: Users can view the supplier name, the total amount in Rupiah, and the specific creation and due dates for each order.
5. Monitor Progress: The table provides a snapshot of operational progress, including the number of returns, invoices, and deliveries associated with each order.
6. Check Status: Users can quickly identify the current state of an order (e.g., Draft, Sent, Delivered) via a color-coded status badge and verify if the order is officially closed using a simple check or cross icon.

1.3 Key Concepts

- Read-Only Display: All information presented in the table is for viewing purposes only; no data can be edited directly from this screen.
- Status Badge: A visual indicator that categorizes the purchase order (e.g., Draft, Cancelled, Sent, or Delivered) to help users understand the current lifecycle stage of the order.
- Closed Indicator: A visual icon (Check or X) that provides an immediate "at-a-glance" confirmation of whether the purchase order process is complete.
- Currency Formatting: All monetary values are automatically formatted in Indonesian Rupiah (IDR) for consistency and readability.

1.4 Business Value

This feature improves operational efficiency by providing procurement and finance teams with a clear, high-level overview of fixed asset spending. By consolidating key metrics—such as delivery counts, invoice status, and return history—into a single view, users can easily track asset acquisition progress and identify which orders require attention without needing to open each record individually.

BUSINESS REQUIREMENTS DOCUMENT

Company - New Stock Outgoing Product Table Card

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Frontend

1.1 Overview

The "New Stock Outgoing Product Table" is the central component used to manage the list of products being removed from inventory. It provides a structured way for users to input product details, specify quantities, and assign expense accounts for each item. The table is designed to be user-friendly, offering both manual entry and bulk file upload capabilities, while ensuring data accuracy through automated calculations and validation checks.

1.2 Step-by-Step Flow

1. Initiation: The user begins with an empty table and can either click "Add Product" to create a new row manually or use the "Upload Outgoing File" button to import multiple products at once.
2. Product Selection: When a product is selected via the search bar, the system automatically populates the "Stock Qty" (current availability) and "Average Cost" fields for reference.
3. Data Entry: The user enters the "Order Qty" (the amount to be removed) and selects the appropriate "Expense Account" from a dropdown menu.
4. Automatic Calculation: As the user enters the quantity, the system instantly calculates the "Amount" (Quantity × Average Cost) and updates the "Total" row at the bottom of the table.
5. Validation: Before saving the document, the system verifies that:

* At least one product line has been added.

* All required fields (Product, Quantity, Expense Account) are filled.

* The "Order Qty" does not exceed the available "Stock Qty."

1.3 Key Concepts

- Computed Fields: Values like "Amount" and "Total" are automatically calculated by the system based on user input, reducing manual errors.
- Read-Only Data: Information such as "Stock Qty" and "Average Cost" is pulled directly from the system to guide the user, but cannot be manually edited.
- Bulk Upload: A feature that allows users to download a template, fill it out offline, and upload it to populate the table instantly.
- Validation Rules: Built-in safeguards that prevent the document from being saved if the data is incomplete or if the requested quantity exceeds current stock levels.

1.4 Business Value

- Efficiency: The bulk upload feature and automatic calculations significantly reduce the time required to prepare stock outgoing documents.
-

Accuracy: By displaying real-time stock availability and automating cost calculations, the system prevents common data entry mistakes.

- Compliance: The requirement to assign an "Expense Account" to every line ensures that inventory movements are correctly categorized for accounting and reporting purposes.
- Reliability: The validation logic ensures that inventory levels remain accurate by preventing the removal of more stock than is currently available.

BUSINESS REQUIREMENTS DOCUMENT

Company - New Stock Outgoing Form Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Stock Outgoing Form Card" is the primary header component used when initiating a new stock outgoing document in the Lumi ERP system. This form captures essential administrative details—such as the origin of the stock, relevant dates, and associated work orders—to ensure that outgoing inventory is tracked accurately from the moment the process begins.

1.2 Step-by-Step Flow

1. Document Identification: The system displays a read-only document number field. This is automatically generated by the server upon saving, so no manual entry is required.
2. Select Source Location: The user selects the origin (store or warehouse) from a required dropdown menu. This selection is critical, as it determines the available stock and costs for the rest of the document.
3. Set Administrative Details: The user may optionally enter a due date and a custom reference number for their own internal tracking.
4. Link Work Orders: Once a source location is selected, the user can search for and attach one or more service work orders. The system will only suggest work orders that are associated with the chosen source location.
5. Add Notes: The user can provide additional context or instructions in the optional notes field, which remains editable even after the initial form submission.

1.3 Key Concepts

- Source Location: The specific store or warehouse from which inventory is being removed. This is the only mandatory field, as it acts as the "anchor" for all subsequent data.
- Work Order Picker: A smart search tool that filters available work orders based on the selected source location, ensuring that only relevant tasks can be linked to the outgoing stock.
- Validation: The system enforces data integrity by requiring the source location before allowing the user to search for work orders, preventing mismatched data.
- Auto-Generation: The system handles document numbering automatically, reducing manual data entry errors and ensuring consistent record-keeping.

1.4 Business Value

- Data Accuracy: By requiring the source location first, the system ensures that inventory and cost calculations are always tied to the correct physical location.
- Operational Efficiency: The smart search for work orders saves time by filtering out irrelevant data, allowing staff to quickly link outgoing stock to specific service tasks.
-

Improved Traceability: The combination of reference numbers, due dates, and notes provides a clear audit trail, making it easier for management to track why and when stock was moved.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Workflow Status Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order Workflow Status component provides a clear, visual way to track the progress of a purchase order. By displaying the order's journey through three distinct stages, users can immediately identify the current status of an order and see which steps have already been completed.

1.2 Step-by-Step Flow

1. Draft: The order is initially created. This is the starting point of the workflow.
2. Store Confirmed: Once the order is reviewed and confirmed by the store, the status advances to this stage.
3. Store Received: The final stage, indicating that the order has been successfully received by the store.

As the order moves through these stages, the component updates visually:

* Completed Steps: Any stage that has already been finished is marked with a checkmark icon.

* Current Step: The stage the order is currently in is highlighted in blue to draw attention.

* Upcoming Steps: Any future stages that have not yet been reached remain in a neutral, pending state.

1.3 Key Concepts

- Workflow Status: The specific stage an order currently occupies within the three-step lifecycle.
- Visual Indicators: The use of icons (checkmarks vs. bullets) and colors (blue for active) to communicate progress at a glance.
- Chevron Separators: The arrow icons placed between steps to visually represent the forward-moving progression of the order.

1.4 Business Value

This component improves operational transparency by eliminating guesswork regarding the status of franchise orders. By providing a standardized, easy-to-read progress tracker, staff can quickly identify bottlenecks or confirm that an order is moving through the system as expected, ultimately leading to better inventory management and more efficient communication between the franchise and the central office.

BUSINESS REQUIREMENTS DOCUMENT

FPO (Standard) New - Add Discount for a Product

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Discount" feature provides a user-friendly interface to apply price reductions to specific products within the inventory system. This tool allows staff to set discounts either as a fixed monetary amount (IDR) or as a percentage, while automatically calculating the final price in real-time to ensure accuracy before saving.

1.2 Step-by-Step Flow

1. Identify Product: The modal opens, displaying the specific product name and SKU to ensure the user is editing the correct item.
2. View Base Price: The system displays the current price (including tax) in a read-only field for reference.
3. Select Discount Type: The user chooses whether to apply the discount as a flat currency amount (IDR) or a percentage (%).
4. Enter Discount Value: The user inputs the discount value. The system validates this input immediately to prevent negative numbers or percentages exceeding 100%.
5. Toggle Tax Status: The user can check a box to indicate if the discount calculation should account for tax.
6. Review Final Price: The system automatically calculates and displays the "Final Price" based on the inputs provided.
7. Save or Cancel: The user clicks "Save" to apply the changes to the product or "Cancel" to discard the inputs and close the window.

1.3 Key Concepts

- Discount Type: A toggle that determines if the discount is calculated as a fixed currency deduction or a percentage of the total price.
- Real-time Calculation: The system instantly updates the "Final Price" field as the user modifies the discount value or type, providing immediate feedback.
- Input Validation: Built-in safety checks that prevent invalid entries, such as negative discounts or percentages greater than 100%.
- Read-only Fields: Specific fields (like the original price and final price) are locked from manual editing to ensure data integrity and prevent calculation errors.

1.4 Business Value

This feature streamlines the inventory management process by removing the need for manual price calculations. By providing an automated, validated interface, it reduces the risk of human error during sales or promotional activities, ensures consistent pricing, and saves time for staff when updating product information.

2. Logic

2.1 Overview

The "Add Discount" feature for the Lumi ERP inventory system is designed to streamline how staff apply price reductions to specific items. When a user selects a product to discount, this feature automatically opens a dedicated window that pre-fills the necessary product information, ensuring accuracy and saving time by eliminating the need for manual data entry.

2.2 Step-by-Step Flow

1. Triggering the Action: The user selects a specific product from the inventory list to apply a discount.
2. Data Retrieval: The system automatically captures the selected product's unique identifier (SKU), its name, and its current price from the inventory row.
3. Information Mapping: The system maps this captured information into the "Add Discount" window.
4. Display: The discount window opens, clearly showing the product details so the user can confirm they are applying the discount to the correct item before proceeding.

2.3 Key Concepts

- Product Context: The specific set of information (SKU, name, and price) associated with an item that is passed from the inventory list to the discount tool.
- Data Mapping: The internal process of ensuring that the information from the inventory list is correctly labeled and placed into the corresponding fields in the discount window.
- Initialization: The automatic "setup" phase that occurs the moment the window opens, ensuring all relevant product data is ready for the user immediately.

2.4 Business Value

This feature improves operational efficiency and reduces human error. By automatically pulling product details into the discount window, staff members avoid the risk of applying a discount to the wrong item or misreading the current price. This creates a smoother, more reliable workflow for managing inventory pricing adjustments within the Lumi ERP system.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal New Table Columns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order table is a dynamic interface designed to help users build a list of products for internal purchase orders. It allows users to add or remove product rows, search for specific items, and input quantities and pricing. The system automatically handles calculations for individual line items and the overall order total, ensuring accuracy and efficiency during the data entry process.

1.2 Step-by-Step Flow

1. Add Items: The user begins with an empty row and can click the "Add Product" button to include additional items in the order.
2. Search and Select: The user searches for a product by typing at least three characters. Once selected, the system automatically populates the "Store Quantity" field.
3. Input Details: For each product, the user manually enters the "Order Quantity," "Supply Price," and any necessary "Store Remarks."
4. Automatic Calculation: As the user enters quantities and prices, the system instantly calculates the "Amount" for that specific row.
5. Review Total: The system maintains a running total at the bottom of the table, which updates automatically whenever a row is modified.
6. Manage Rows: If a user needs to remove an item, they can click the "X" button on the corresponding row to delete it from the order.

1.3 Key Concepts

- Dynamic Row Management: The ability to add or remove product entries on the fly, providing flexibility for orders of any size.
- Auto-Calculation: Features that reduce manual math errors by automatically computing row totals and the grand total based on user input.
- Data Validation: Built-in safeguards that ensure quantities are positive numbers and required fields (like remarks and prices) are filled out before the order is processed.
- Smart Search: A search function that triggers after three characters are entered, ensuring the user selects the correct product from the database.

1.4 Business Value

This feature streamlines the franchise procurement process by replacing manual entry with a guided, automated interface. By automating calculations and providing immediate feedback on inputs, the system reduces the likelihood of human error, saves time for staff, and ensures that purchase order data is consistent and accurate before it is submitted to the inventory system.

2. Logic

2.1 Overview

This feature introduces a structured data entry table for franchise purchase orders within the Lumi ERP system. It provides a standardized way for users to input product details, ensuring that every item added to an order is accurately recorded, validated, and formatted before it is submitted to the system.

2.2 Step-by-Step Flow

1. Initialize Row: When a user begins adding a new item to a purchase order, the system generates a blank row with default values (zero quantities and empty text fields) to ensure a consistent starting point.
2. Data Entry: The user fills in the specific product details, including the product identifier, current store stock, the quantity they wish to order, the supply price, and any relevant notes.
3. Mapping: As the user enters information, the system maps these inputs to the internal purchase order schema, ensuring the data is organized correctly for the database.
4. Validation: Before the order is finalized, the system performs integrity checks. It confirms that a product has been selected and ensures that the order quantity is a valid, positive number.
5. Submission: Once validated, the item data is accepted and ready to be processed as part of the official franchise purchase order.

2.3 Key Concepts

- Product Identifier: The unique code used to distinguish one specific item from another in the inventory.
- Store Quantity: The amount of a specific product currently held in the franchise store's inventory.
- Order Quantity: The specific amount of a product the franchise is requesting to purchase; this must always be a positive number.
- Supply Price: The cost per unit of the product being ordered.
- Store Remark: An optional text field allowing the user to add specific notes or instructions regarding that particular line item.

2.4 Business Value

-

Data Accuracy: By enforcing validation rules (such as requiring a product ID and positive quantities), the system prevents common entry errors that could lead to incorrect shipments or billing issues.

- Operational Efficiency: Standardizing the input process ensures that franchise staff can quickly and reliably create purchase orders without needing to manually format data.
- System Integrity: Mapping inputs directly to the internal schema ensures that the data remains consistent across the entire ERP platform, making it easier to track inventory and financial records accurately.

3. Data

3.1 Overview

This feature introduces a new, interactive table for the Lumi ERP system designed to streamline how franchise purchase orders are created. It provides a structured interface where staff can select products and define order quantities, ensuring that all necessary details for a franchise request are captured accurately in one place.

3.2 Step-by-Step Flow

1. Product Selection: The user selects a product from the catalog, which automatically populates the relevant item details.
2. Quantity Entry: The user enters the quantity currently held at the store ("Store Qty") and the quantity they wish to request ("Order Qty").
3. Price Display: The system automatically retrieves and displays the current supply price for the selected product, ensuring the user has up-to-date cost information.
4. Adding Remarks: The user can add any specific notes or instructions for the order in the remarks field.
5. Saving Data: Once the details are entered, the system bundles this information and saves it to the franchise purchase order record.

3.3 Key Concepts

- Product Selector: A tool that allows users to pick items from the inventory catalog, ensuring consistency in product identification.
- Supply Price: The cost of a product, which is automatically pulled from the system to prevent manual entry errors.
- Store Quantity: The current stock level reported by the franchise, used to help determine the necessity of the order.
- Order Quantity: The specific amount of product the franchise is requesting to purchase.
- Remark: A flexible text field for any additional context or special instructions regarding a specific line item.

3.4 Business Value

- Increased Accuracy: By automating the retrieval of supply prices and using a standardized product selector, the system reduces the risk of manual data entry errors.
- Improved Efficiency: Consolidating all order details into a single, intuitive table allows staff to process franchise requests faster.
- Better Inventory Visibility: Capturing both current store stock and requested order quantities provides management with clearer insights into franchise inventory needs and replenishment patterns.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Orders - Internal New Order Form Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Franchise Purchase Order form is a new interface component designed to streamline the creation of internal purchase orders within the Lumi ERP system. This form allows users to specify the origin of goods (warehouse and supplier) and the destination (store), while providing optional fields for tracking and scheduling. The system ensures data integrity by enforcing mandatory selections before an order can be submitted.

1.2 Step-by-Step Flow

1. Document Identification: The system automatically generates a unique document number for the order, which is displayed as a read-only field.
2. Required Selections: The user must select a source warehouse, a destination store, and a supplier from the provided dropdown menus. These fields are validated in real-time to ensure they are not left blank.
3. Optional Details: The user may optionally enter a reference code, select a due date using the calendar picker, and add any relevant notes.
4. Validation: As the user fills out the form, the system performs immediate checks. If a required field is missing, the system flags it to prevent incomplete submissions.
5. Submission: Once all required information is provided, the user clicks the "Create Order" button. The system processes the data and confirms the creation of the purchase order. If the submission fails, the system provides feedback to the user.

1.3 Key Concepts

- Required Fields: Specific data points (Warehouse, Store, and Supplier) that must be provided to successfully create an order.
- Real-time Validation: A feature that checks for errors as the user interacts with the form, providing immediate feedback rather than waiting until the end.
- System-Generated Fields: Information, such as the Document Number, that is handled automatically by the software and does not require user input.
- Dropdown Integration: Menus that pull current, accurate data directly from the system's warehouse, store, and supplier databases.

1.4 Business Value

This feature standardizes the purchase order process, reducing manual entry errors and ensuring that all necessary logistics data is captured consistently. By automating the document numbering and integrating live data

for warehouses and stores, the form minimizes administrative overhead and ensures that inventory movements are accurately tracked from the moment an order is initiated.

2. Logic

2.1 Overview

The Franchise Purchase Order form is a new internal tool designed to streamline how inventory is requested and moved between locations. This feature provides a structured interface for staff to create purchase orders by selecting the source warehouse, the destination store, and the supplier, while also allowing for optional details like reference numbers, delivery dates, and internal notes.

2.2 Step-by-Step Flow

1. Data Entry: The user fills out the form by selecting the required warehouse, store, and supplier from dropdown menus. They may also optionally provide a reference code, a due date, and any relevant notes.
2. Validation: The system checks that the three required fields (warehouse, store, and supplier) have been completed. If any are missing, the system will prompt the user to provide the necessary information before proceeding.
3. Data Formatting: Once validated, the system organizes the information into a standardized format, ensuring dates and text are correctly prepared for the system's records.
4. Submission: The system sends the completed order to the central database.
5. Confirmation: Upon successful submission, the system confirms the order has been created and assigns it a unique identifier for tracking purposes.

2.3 Key Concepts

- Franchise Purchase Order: A formal request document used to track the movement of inventory from a supplier or warehouse to a specific franchise store.
- Required Fields: Essential pieces of information (Warehouse, Store, and Supplier) that must be provided to ensure the order can be processed and tracked accurately.
- Reference Code: An optional, user-defined identifier (such as an internal tracking number) used to help staff easily locate or cross-reference the order later.
- Due Date: An optional field that allows the user to specify when the inventory is expected to arrive, assisting with better scheduling and inventory planning.

2.4 Business Value

This feature centralizes the purchase order process, reducing manual errors by enforcing the collection of critical data points. By standardizing how orders are created, the business gains better visibility into inventory movement, improves the accuracy of supply chain tracking, and ensures that all stakeholders—from warehouse managers to store owners—have a clear, consistent record of incoming stock.

3. Data

3.1 Overview

The Franchise Purchase Order form is a new feature within the Lumi ERP system designed to streamline how inventory is moved or ordered between locations. This form allows users to create a formal request by selecting the source warehouse, the destination store, and the supplier, while also providing space for reference codes, delivery deadlines, and additional notes.

3.2 Step-by-Step Flow

1. Data Loading: When the form opens, the system automatically retrieves the current lists of available suppliers, stores, and warehouses to ensure the user is selecting from up-to-date information.
2. Selection: The user selects the source warehouse and the destination store from the provided lists. The store selection includes a search feature to help users quickly find the correct location.
3. Optional Details: The user selects a supplier (if applicable) and enters a unique reference code for the order.
4. Scheduling and Notes: The user sets the required delivery date and adds any necessary comments or instructions in the notes field.
5. Submission: Once the user submits the form, the system packages all selected and entered information into a formal purchase order and saves it to the inventory database.

3.3 Key Concepts

- Source Warehouse: The specific facility where the inventory is currently held or being shipped from.
- Destination Store: The specific franchise location that will receive the inventory.
- Reference Code: A unique identifier or tracking number assigned to the order for easy record-keeping.
- Due Date: The specific date by which the purchase order is expected to be fulfilled.
- Supplier: An optional entity that may be associated with the order if the inventory is being sourced externally rather than internally.

3.4 Business Value

This feature centralizes the purchase order process, reducing manual data entry errors and ensuring that inventory movements are tracked accurately across the franchise network. By providing a standardized form, the system ensures that all necessary information—such as delivery deadlines and reference codes—is captured consistently, which improves communication between warehouses and stores and leads to better inventory management.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Store Work Order Search and Filter Toolbar

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Stock Store Work Order Toolbar is a search and filtering interface designed to help users quickly locate specific work orders within the Lumi ERP system. By providing a centralized set of controls, users can narrow down large lists of inventory-related work orders based on specific criteria, such as order IDs, status, location, or date ranges.

1.2 Step-by-Step Flow

1. Input Criteria: The user enters or selects information into the available fields, including specific Stock Order IDs, Service Work Order IDs, status, store location, warehouse location, and a date range.
2. Initiate Search: Once the desired filters are set, the user clicks the "Search" button (identified by a magnifying glass icon).
3. Validation: The system automatically checks the date range to ensure the "From Date" is not later than the "To Date." If the dates are invalid, the system alerts the user to correct them.
4. Execute Search: If the validation passes, the system processes the selected filters and updates the inventory view to display only the matching work orders.

1.3 Key Concepts

- Filter Fields: Specific data points (like Order ID or Warehouse) used to refine search results.
- Date Range Validation: A built-in safety check that prevents search errors by ensuring the start date occurs before or on the end date.
- Search Action: The trigger that sends the user's selected criteria to the system to retrieve the relevant data.

1.4 Business Value

This feature significantly improves operational efficiency by reducing the time spent manually scrolling through inventory records. By allowing users to filter by precise criteria—such as specific stores or warehouses—staff can quickly identify the status of work orders, resolve inventory discrepancies faster, and maintain better oversight of stock movements across the organization.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Stock Order Service Orders Search and Filter Toolbar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Order Service Order Toolbar is a user-friendly interface component designed to help staff quickly locate specific inventory records within the Lumi ERP system. By providing a centralized set of filters, users can narrow down large lists of stock and service orders based on location, timing, specific identification numbers, or current processing status.

1.2 Step-by-Step Flow

1. Define Criteria: The user interacts with the toolbar to input or select filter criteria, including the Warehouse, Store, Date Range, Service Order ID, Stock Order ID, and Status.
2. Real-time Validation: As the user selects dates, the system automatically checks that the "From Date" is not later than the "To Date." If an invalid range is entered, the system flags an error.
3. Apply Filters: Once the desired criteria are set, the user clicks the "Search" button.
4. Execute Query: The system processes the selected filters and updates the inventory display to show only the records that match the user's specific requirements.

1.3 Key Concepts

- Filter Criteria: The specific data points (such as location or ID) used to refine search results.
- Date Range Validation: A built-in safety check that ensures the search timeframe is logical (i.e., the start date must come before the end date).
- Inventory Records: The underlying data being searched, which includes both stock-related and service-related order information.
- Status Filtering: A way to view orders based on their current stage in the workflow (e.g., pending, completed, or in-progress).

1.4 Business Value

This feature significantly improves operational efficiency by reducing the time staff spend manually searching through inventory lists. By allowing users to pinpoint exact orders using multiple criteria, the toolbar minimizes human error and ensures that warehouse and store managers can access critical order information instantly, leading to faster decision-making and better inventory oversight.

BUSINESS REQUIREMENTS DOCUMENT

Stock - Stock Order Sales Retail Search and Filter Toolbar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Stock Order Sales Retail Search and Filter Toolbar is a user-friendly interface component designed to help staff quickly locate specific stock order records within the Lumi ERP system. By providing a centralized set of controls, users can narrow down large lists of data based on specific criteria such as location, order number, timeframes, and current status.

1.2 Step-by-Step Flow

1. Define Criteria: The user interacts with the toolbar to input or select their desired search parameters. This includes choosing a specific warehouse, entering a unique stock order number, selecting a store, picking a status, or choosing a sales type.
2. Set Timeframe: The user selects a "From Date" and a "To Date" to define the specific period they wish to review.
3. Trigger Search: The user clicks the "Search" button (identified by a magnifying glass icon).
4. Validation: The system automatically checks the date range. If the "From Date" is set after the "To Date," the system alerts the user to correct the error before proceeding.
5. Apply Filters: Once validated, the system applies all selected criteria to the inventory records and displays the relevant results.

1.3 Key Concepts

- Filter Criteria: The specific data points (like Warehouse, Store, or Status) used to refine a search and reduce the number of records shown.
- Date Range Validation: A built-in safety check that ensures the search timeframe is logical (i.e., the start date cannot occur after the end date).
- Search Execution: The final action that triggers the system to process the selected filters and update the view for the user.

1.4 Business Value

This feature significantly improves operational efficiency by reducing the time staff spend manually searching for stock orders. By allowing users to filter by precise categories—such as specific stores or order statuses—the tool ensures that warehouse and retail teams can access the exact information they need to manage inventory, track sales, and resolve order-related inquiries quickly and accurately.

BUSINESS REQUIREMENTS DOCUMENT

Company - Purchase Return Fixed Assets Search and Filter Bar

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Purchase Return Filter Bar is a search interface designed to help users quickly locate specific fixed asset return records within the Lumi ERP system. Instead of displaying all records at once, this tool allows users to narrow down the list using specific criteria. The system is designed to be efficient: it waits for the user to finalize their search criteria and click the "Search" button before retrieving the relevant data, ensuring a smooth and controlled browsing experience.

1.2 Step-by-Step Flow

1. Input Criteria: The user enters or selects information into one or more of the available fields: Document Number, Status, Supplier, or a Date Range (From/To).
2. Validation: When the user clicks the "Search" button, the system automatically checks the date range. If the "From" date is set after the "To" date, the system alerts the user to correct the error before proceeding.
3. Data Retrieval: Once the inputs are validated, the system sends a request to the server using the selected criteria.
4. Display: The system fetches the matching records and updates the inventory list on the screen to show only the items that meet the user's search requirements.

1.3 Key Concepts

- Document Number: A text field used to find specific records by their unique identifier.
- Status: A dropdown menu that allows users to filter returns based on their current lifecycle stage (e.g., Draft, Sent, Approved, or Cancelled).
- Supplier: A dropdown menu to filter returns by the specific vendor associated with the transaction.
- Date Range: Two date pickers that allow users to define a specific timeframe for when the return was created.
- Explicit Search: A design choice where the system does not automatically refresh the list while the user is typing; the user must click "Search" to trigger the update, which prevents unnecessary system load.

1.4 Business Value

- Improved Productivity: Users can find specific return documents in seconds rather than scrolling through long lists of inventory data.
- Data Accuracy: Built-in validation prevents common errors, such as entering an invalid date range, ensuring that search results are always meaningful and accurate.
- Streamlined Workflow: By providing clear filtering options, the system helps staff manage the return process more effectively, whether they are checking the status of a pending return or auditing past transactions.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/franchise-purchase-orders?{filters}&{pagination}&{sorting}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for authorized users to retrieve a list of franchise purchase orders. The system automatically ensures that users only see orders belonging to their specific company. The results are flexible, allowing users to filter by status, order type, or date range, and to sort or paginate the results to manage large volumes of data efficiently.

1.2 Step-by-Step Flow

1. Authentication: The system identifies the user and automatically restricts the search to their company's purchase orders.
2. Parameter Processing: The system receives your requested filters (such as status or date range), sorting preferences, and pagination settings (which page to show and how many items per page).
3. Validation: The system checks that your request is valid—for example, ensuring that a "start date" is not set after an "end date."
4. Data Retrieval: The system searches the database for all orders matching your criteria and calculates the total number of matching records.
5. Calculation: For each order found, the system calculates the total order value and the total received value based on the individual items within that order.
6. Response: The system returns the list of orders along with the total count of matching records. If no orders match your filters, it returns an empty list rather than an error.

1.3 Key Concepts

- Filtering: Narrowing down the list of orders by specific criteria like current status, order type, or a specific timeframe.
- Pagination: Breaking a large list of orders into smaller, manageable pages to improve performance and readability.
- Sorting: Organizing the list by a specific field (like date) in either ascending or descending order.
- Data Enrichment: The process of calculating "order amount" and "received amount" on the fly for each order, ensuring the financial totals are always up-to-date based on the latest line items.
- Scope: A security measure that ensures users can only access data associated with their own company.

1.4 Business Value

This feature empowers franchise managers and administrators to efficiently track procurement activities. By providing a robust search and filter tool, users can quickly identify pending orders, review historical purchase data, and monitor financial totals without needing to manually aggregate information. The automated scoping ensures data security, while the pagination and sorting capabilities ensure the system remains fast and responsive even as the volume of purchase orders grows.

2. Data

2.1 Overview

This feature provides a way to retrieve a list of franchise purchase orders through our system. It is designed to be flexible, allowing users to search for specific orders, sort them by date or order number, and view them in manageable pages. The system automatically calculates the total financial value of each order and the total value of items received based on the individual line items associated with that order.

2.2 Step-by-Step Flow

1. Scope Identification: The system identifies the company associated with the user making the request to ensure they only see their own franchise data.
2. Filtering: The system applies any requested filters, such as order type, status, or a specific date range (created date).
3. Counting: Before showing the results, the system calculates the total number of orders that match the filters to help with navigation.
4. Sorting: The system organizes the list based on the user's preference (e.g., by date or order number) in either ascending or descending order. If no preference is provided, it defaults to showing the newest orders first.
5. Pagination: The system limits the number of results returned at once to ensure the application remains fast and responsive.
6. Data Calculation: For every order in the list, the system calculates the total order amount and the total received amount by summing up the individual line items.
7. Response: The system returns the final list of orders along with the total count of matching records.

2.3 Key Concepts

– Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.

– Filtering: The ability to narrow down a large list of records based on specific criteria, such as status or date.

–

Aggregation: The process of calculating totals (like order value) by combining data from multiple related line items.

- Sorting: The ability to arrange the list in a specific order, such as by date or reference number.

2.4 Business Value

This feature empowers franchise managers and administrators to efficiently track and audit their procurement activities. By providing real-time visibility into order statuses and financial totals, it reduces the manual effort required to reconcile purchase orders. The inclusion of flexible filtering and sorting ensures that users can quickly find the specific information they need, supporting better inventory management and financial oversight.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-returns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides the "Stock Returns" list for the Inventory module. It allows users to view and filter a list of stock items being returned from stores to warehouses. The system ensures that only relevant "warehouse" return records are displayed and provides flexible search options to help staff quickly locate specific return transactions.

1.2 Step-by-Step Flow

1. Validation: The system checks that the request is specifically for "warehouse" returns and verifies that the provided date range (if any) is logical (i.e., the start date is not after the end date).
2. Data Retrieval: The system gathers the necessary stock return records, including the name of the user who created each entry.
3. Filtering: The system applies any user-selected filters, such as specific reference numbers, date ranges, store locations, warehouse destinations, or current workflow statuses.
4. Sorting and Pagination: The final list is sorted by date (newest first) and divided into pages to ensure the interface remains fast and easy to navigate.
5. Response: The system returns the requested list of records or provides an error message if the request was invalid, unauthorized, or if a system error occurred.

1.3 Key Concepts

- Stock Return: A record representing the movement of inventory from a store back to a warehouse.
- Workflow State: The current status of a return (e.g., pending, approved), which helps track the progress of the return process.
- Pagination: A method of breaking a large list of records into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down the list of returns based on specific criteria like date, location, or status.

1.4 Business Value

This feature streamlines inventory management by providing a centralized, searchable view of all stock returns. By allowing staff to filter by store, warehouse, and status, the system reduces the time spent searching for specific transactions, improves accuracy in tracking returned goods, and ensures that inventory records remain up-to-date and transparent across different locations.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-opname

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of stock opname (inventory count) records from the system. It is designed to help inventory managers track and reconcile stock levels by allowing them to view scheduled counts, filter them by specific warehouses or timeframes, and manage large lists through pagination.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to view stock opname records.
2. Parameter Collection: The system collects your search criteria, including the specific warehouse, the start and end dates for the schedule, and pagination settings (which page to view and how many records to show).
3. Data Retrieval: The system searches the inventory database using the provided filters to find matching stock opname records.
4. Result Delivery: The system returns the requested list of records. If the request is invalid or an error occurs, the system provides an appropriate error message.

1.3 Key Concepts

- Stock Opname: A formal process of counting physical inventory to ensure it matches the records in the system.
- Filtering: The ability to narrow down the list of records by selecting a specific warehouse or a date range (e.g., "show me all counts scheduled for next week").
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Authentication/Authorization: Security measures that ensure only verified users with the correct access rights can view sensitive inventory data.

1.4 Business Value

- Improved Inventory Accuracy: By making it easy to retrieve and review scheduled stock counts, the business can ensure inventory records remain accurate and up-to-date.
- Operational Efficiency: Users can quickly find specific inventory count records without manually searching through the entire database, saving time during daily operations.
- Scalability: The use of pagination ensures that the system remains fast and responsive, even as the number of inventory records grows over time.
-

Data Security: Built-in access controls ensure that inventory information is only visible to authorized personnel, protecting sensitive business data.

2. Data

2.1 Overview

This feature provides a way to retrieve a list of "stock opname" records—the formal process of counting and reconciling physical inventory against system records. By using this tool, warehouse managers and inventory staff can easily view scheduled or completed stock counts, filter them by specific locations or timeframes, and manage large volumes of data through organized, paginated lists.

2.2 Step-by-Step Flow

1. Request Initiation: The user requests the list of stock opname records.
2. Applying Filters: The system checks if the user has requested specific criteria, such as a particular warehouse or a specific date range.
3. Data Retrieval: The system searches the database for records matching the provided filters.
4. Sorting: The results are automatically sorted so that the most recently scheduled stock counts appear at the top of the list.
5. Pagination: To ensure the system remains fast and easy to read, the results are broken into manageable pages. The system also calculates the total number of records to help the user navigate through the pages.
6. Display: The final list of records is returned to the user.

2.3 Key Concepts

- Stock Opname: The process of physically counting inventory items to ensure the actual stock matches the quantities recorded in the ERP system.
- Filtering: A tool that allows users to narrow down the list of records by selecting a specific warehouse or a date range, making it easier to find relevant information.
- Pagination: A method of splitting a large list of data into smaller, separate pages to improve performance and readability.
- Reconciliation: The act of comparing physical inventory counts with system data to identify and resolve discrepancies.

2.4 Business Value

This feature streamlines inventory management by providing clear visibility into stock reconciliation activities. By allowing users to filter and sort these records, the system reduces the time spent searching for specific audit data. Furthermore, the use of pagination ensures that the application remains responsive and user-friendly, even as the number of inventory audits grows over time, ultimately supporting more accurate inventory tracking and better operational control.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-opname?{filters}&{pagination}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a search and retrieval function for the "Stock Opname" list within the Lumi ERP system. It allows users to filter stock orders based on specific criteria—such as reference codes, date ranges, store locations, and current workflow status—to quickly locate relevant inventory records.

1.2 Step-by-Step Flow

1. Validation: The system first checks that the request is specifically for "warehouse" stock. If this is missing or incorrect, the request is rejected.
2. Initialization: The system prepares to search the database for all records categorized as "stock orders."
3. Applying Filters: The system checks which optional filters (reference code, date range, store ID, or status) have been provided by the user. Only the filters with active values are applied to the search.
4. Refining Results:

– If a reference code is provided, the system searches for partial matches in both the internal reference code and the supplier's reference code.
– Date ranges are applied to include all records created on or between the selected start and end dates.

5. Data Retrieval: The system executes the search and returns the matching list of stock orders to the user interface. If an unexpected error occurs during this process, the system notifies the user that the lookup failed.

1.3 Key Concepts

– Stock Type: A mandatory category filter that ensures the system only retrieves relevant warehouse-related stock orders.
– Partial Matching: A search method where the system finds records containing the provided text, even if it is only a portion of the full reference code.
– Workflow State: The current status of a stock order (e.g., pending, received, or completed), which can be used to narrow down search results.
– Inclusive Date Filtering: A search logic where the "from" and "to" dates are included in the results, ensuring no records from those specific days are missed.

1.4 Business Value

This feature improves operational efficiency by allowing warehouse staff and managers to quickly pinpoint specific stock orders without manually scanning through large datasets. By providing flexible filtering options, the system

ensures that users can generate accurate reports and monitor inventory status in real-time, leading to better decision-making and reduced administrative overhead.

2. Data

2.1 Overview

The Stock Opname feature provides a way for users to search and retrieve a list of warehouse stock orders from the system. By using various filters, users can quickly locate specific inventory records based on reference codes, date ranges, store locations, or the current processing status of the order.

2.2 Step-by-Step Flow

1. Initiate Request: The user triggers a search, which sends a request to the system. This request must specify that it is for "warehouse" stock to ensure the correct data is retrieved.
2. Apply Filters: The system checks for any additional search criteria provided by the user:

* Reference Code: Searches for partial matches in both the internal reference code and the supplier’s reference code.

* Date Range: Filters records created between a specific start and end date (inclusive).

* Store ID: Limits results to a specific store location.

* Status: Filters records based on their current workflow state (e.g., pending, received).

3. Data Retrieval: The system queries the database using the provided filters.
4. Response:

* If successful, the system returns the matching list of stock orders to be displayed in the table.

* If the request is invalid (e.g., missing the required "warehouse" type) or if a system error occurs, the user receives an appropriate error notification.

2.3 Key Concepts

- Stock Opname: A process for verifying inventory levels; in this system, it refers to the management of warehouse stock orders.
- Reference Code: A unique identifier for an order, which can be searched by either the internal system code or the supplier's provided code.
- Workflow State: The current stage of an order in the business process (e.g., whether it is still being processed or has been completed).
-

Inclusive Filtering: When searching by date, the system includes records from both the start and end dates selected by the user.

2.4 Business Value

This feature improves operational efficiency by allowing warehouse staff and managers to quickly find and audit specific stock orders. By providing flexible search options, users spend less time manually scrolling through lists and can instead pinpoint the exact information needed to manage inventory levels accurately and resolve discrepancies faster.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/franchise-purchase-returns?{filters}&{pagination}&{sorting}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of "Franchise Purchase Returns." It is designed to power the Franchise tab within the Franchise Purchase Returns page. The tool allows users to search, filter, and view these returns in a paginated format, ensuring that users only see data relevant to their specific company.

1.2 Step-by-Step Flow

1. Authentication: The system verifies the user's identity. If the user is not logged in or lacks proper authorization, the request is denied.
2. Parameter Collection: The system gathers the user's search criteria, such as specific stores, suppliers, warehouses, workflow statuses, or date ranges. It also notes which page of results the user is requesting.
3. Data Scoping: The system automatically restricts the search to only include "franchise-related" returns that belong to the user's company.
4. Filtering & Sorting: The system applies the user's specific filters (like searching by a reference code prefix) and sorts the results so that the most recently created returns appear at the top.
5. Result Delivery: The system returns the requested list of data. If an unexpected error occurs during this process, the system provides an error notification.

1.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable pages (e.g., 20 items per page) to improve performance and readability.
- Workflow State: The current status of a return (e.g., pending, approved, or completed), which can be used to filter the list.
- Reference Code Search: A feature that allows users to find specific returns or orders by typing the beginning of their identification numbers.
- Data Isolation: A security measure ensuring that users can only access information belonging to their own company, preventing unauthorized access to other franchise data.

1.4 Business Value

This feature streamlines inventory management by providing franchise managers with a dedicated, high-performance view of purchase returns. By offering robust filtering and sorting capabilities, it reduces the time spent searching for specific records and ensures that staff can quickly track the status of returns across different stores and warehouses. The built-in security ensures that sensitive company data remains protected and isolated.

2. Data

2.1 Overview

This feature provides a way for the system to retrieve a list of franchise-related purchase returns. It is designed to power the "Franchise" tab within the Franchise Purchase Returns page, allowing users to view, search, and filter their return records efficiently. The system ensures that users only see data belonging to their specific company and organizes the results so that the most recent returns appear first.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies the user's identity to ensure they only access records belonging to their company.
2. Scope Filtering: The system automatically narrows the search to only include "franchise-external" and "franchise-internal" return types.
3. Applying User Filters: The system applies any specific criteria provided by the user, such as the return status (workflow state), specific store, supplier, warehouse, or date ranges.
4. Search Matching: The system looks for records that match the provided Return Number or Order Number prefixes.
5. Sorting and Pagination: The system sorts the matching records by date (newest first) and divides them into pages based on the requested page number and limit.
6. Data Retrieval: The system fetches the requested page of data and calculates the total count of matching records to support pagination controls in the user interface.

2.3 Key Concepts

- Franchise Purchase Return: A record representing stock being returned within the franchise business flow.
- Workflow State: The current status of a return (e.g., pending, approved, completed), used to filter the list.
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Company Scoping: A security measure that ensures users can only view data associated with their own organization.
- Prefix Search: A search method where the system finds records starting with the specific characters entered by the user (e.g., searching for "RET-001" will find all returns starting with those characters).

2.4 Business Value

This feature enables franchise managers and staff to quickly locate and monitor return activity. By providing robust filtering and sorting capabilities, it reduces the time spent searching for specific transactions and ensures that users have an accurate, up-to-date view of their inventory returns. This visibility is essential for maintaining accurate stock levels and managing franchise-supplier relationships effectively.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/discrepancy-stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Discrepancy Stocks" feature provides a way to view and manage inventory discrepancies specifically for store locations. This tool allows users to retrieve a list of items where the recorded stock does not match the expected levels. To keep the data manageable and relevant, the system allows users to filter these reports by specific products, status, or date ranges, and presents the information in a paginated format.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the user is logged in. If the user is not authenticated, access is denied.
2. Scope Identification: The system automatically identifies the user's company and restricts the search to "store" entities, ensuring users only see data relevant to their specific business context.
3. Parameter Processing: The system collects any filters provided by the user (such as a specific product code, report status, or a date range) and sets the pagination preferences (which page to show and how many items per page).
4. Data Retrieval: The system searches the inventory records based on the company, entity type, and any applied filters.
5. Sorting and Delivery: The results are sorted by the date they were created (newest first) and returned to the user. If no records match the criteria, an empty list is provided.

1.3 Key Concepts

- Discrepancy Stock: An inventory record indicating a mismatch between expected and actual stock levels for a specific product.
- Filtering: The ability to narrow down the list of discrepancies by product code (SKU), current status, or a specific timeframe.
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Scoped Access: A security measure that ensures users can only view data belonging to their own company and store locations.

1.4 Business Value

This feature provides transparency into inventory accuracy, allowing store managers to quickly identify and address stock discrepancies. By offering flexible filtering and organized reporting, it helps teams reduce manual effort in tracking down inventory errors, ultimately leading to better stock control and more reliable data for business decision-making.

2. Data

2.1 Overview

The `GET /api/discrepancy-stocks` feature provides a way for users to view a list of inventory discrepancies specifically related to their store locations. This tool is designed to help staff track and manage stock issues by allowing them to search, filter, and browse records through a clean, paginated interface. The system automatically ensures that users only see data relevant to their own company and store entities, maintaining data security and relevance.

2.2 Step-by-Step Flow

1. Authentication & Scoping: When a request is made, the system identifies the user's company and automatically restricts the search to "store" locations. This ensures users cannot access data from other companies or non-store entities.
2. Applying Filters: The system processes any optional filters provided by the user, such as date ranges, specific product names, SKU codes, document reference numbers, or workflow statuses (e.g., draft, responded, or done).
3. Sorting: The resulting list is automatically sorted by the date the record was created, showing the most recent discrepancies at the top.
4. Pagination: To keep the data manageable, the system applies a limit to how many records are shown at once and allows the user to skip through pages of results.
5. Response: The system returns the filtered list of discrepancies. If no records match the criteria, it returns an empty list rather than an error.

2.3 Key Concepts

- Discrepancy Stock: A record representing a mismatch between expected and actual inventory levels for a specific product.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down a large list of records based on specific criteria, such as a date range or a product's status.
- Scope: A security measure that automatically limits the data returned to only what the authenticated user is authorized to see (in this case, their own company's store data).

2.4 Business Value

This feature streamlines inventory management by allowing store managers and staff to quickly identify and address stock discrepancies. By providing flexible search and filter options, users can spend less time hunting for specific reports and more time resolving inventory issues. The automated scoping ensures that sensitive company data remains protected, while the paginated, sorted view ensures that the most urgent or recent discrepancies are always prioritized for review.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-transfers?{filters}&{pagination}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of stock transfers—movements of inventory between warehouses. It is designed to power the "Stock Transfers" list page in the Lumi ERP. The system automatically ensures that users only see data belonging to their own company, and it includes flexible search and navigation tools to help users find specific records quickly.

1.2 Step-by-Step Flow

1. Authentication: The system verifies the user's identity and automatically identifies which company they belong to.
2. Applying Filters: The system checks for any search criteria provided (such as a specific source warehouse, destination warehouse, or transfer status). If no criteria are provided, it prepares to show the full list.
3. Pagination Setup: The system sets a limit on how many records to show at once and determines the starting point (offset) for the current view.
4. Data Retrieval: The system searches the database for all relevant stock transfers, applying the filters and sorting the results by the most recently created items first.
5. Response: The system returns the requested list of transfers along with pagination details (such as the total number of records found), allowing the user interface to display the correct page and navigation buttons.

1.3 Key Concepts

- Filtering: The ability to narrow down the list of transfers by selecting specific warehouses or statuses, making it easier to find relevant information.
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Data Scoping: A security measure that ensures users can only access and view stock transfer records associated with their specific company.
- Offset: A technical term for the starting position in a list; it tells the system how many records to skip before displaying the next set of results.

1.4 Business Value

This feature improves operational efficiency by allowing warehouse managers and staff to quickly locate specific inventory movements. By providing built-in filtering and pagination, the system remains fast and responsive even as the number of stock transfers grows over time. Furthermore, the automatic scoping of data ensures that sensitive company information remains secure and isolated from other organizations using the platform.

2. Data

2.1 Overview

This feature provides a secure way for the system to retrieve a list of stock transfers. It is designed to power the "Stock Transfers" list page, ensuring that users only see data relevant to their specific company. The system automatically handles sorting, filtering, and pagination to ensure the interface remains fast and easy to navigate.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and associated with a valid company. If not, the request is denied.
2. Scope Limitation: The system automatically restricts the search to only include stock transfers belonging to the user's company.
3. Applying Filters: If the user has selected specific criteria (such as a transfer status or a source warehouse), the system applies these filters to narrow down the results.
4. Counting Records: Before showing the results, the system calculates the total number of matching records. This allows the user interface to display accurate page numbers and navigation controls.
5. Sorting and Pagination: The system sorts the transfers by date (newest first) and retrieves only the specific "slice" of data requested (e.g., 20 items per page), ensuring the application performs efficiently.
6. Data Delivery: The system returns the requested list of transfers along with the total count and pagination details to the user interface.

2.3 Key Concepts

- Scoped Access: A security measure that ensures users can only view data belonging to their own organization, preventing unauthorized access to other companies' information.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve system performance and user experience.
- Dynamic Filtering: The ability to refine search results based on specific criteria, such as the status of a transfer or the warehouse it originated from.
- Metadata: Additional information returned with the data (like the total count of records), which helps the front-end application manage navigation without needing to perform extra searches.

2.4 Business Value

This feature ensures that the inventory management process is both secure and efficient. By automating the filtering and pagination of stock transfers, it provides a responsive experience for staff managing warehouse

movements. Furthermore, the built-in company scoping guarantees data privacy and integrity, ensuring that users only interact with the information relevant to their specific business operations.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-reservations

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for authorized users to retrieve a list of current stock reservations within the Lumi ERP system. By using specific search criteria, users can quickly pinpoint reservations for particular products or stores over a defined timeframe.

1.2 Step-by-Step Flow

1. Security Verification: The system first checks that the user is logged in and possesses the necessary permissions to view stock reservation data.
2. Parameter Validation: The system reviews the search criteria provided by the user (such as dates, product details, or store location) to ensure they are formatted correctly.
3. Data Retrieval: If the request is valid, the system searches the inventory database using the provided filters.
4. Response: The system returns the matching list of reservations. If any errors occur during the process (such as invalid input or system issues), the system provides an appropriate error message.

1.3 Key Concepts

- Stock Reservation: A record indicating that a specific quantity of a product has been set aside for a particular store or order.
- Filtering: The ability to narrow down search results by specific attributes, such as a date range, product name, product code (SKU), or store ID.
- Authentication: The process of verifying the identity of the user making the request.
- Authorization: The process of confirming that the verified user has the specific rights required to access reservation data.

1.4 Business Value

This feature improves inventory visibility and operational efficiency. By allowing staff to easily query stock reservations, the business can better track committed inventory, prevent overselling, and improve coordination between warehouse stock and store-level availability. The built-in security ensures that sensitive inventory data remains accessible only to authorized personnel.

2. Data

2.1 Overview

This feature provides a way for authorized users to retrieve a list of current stock reservations within the Lumi ERP system. It allows users to search and narrow down reservation data using specific criteria, such as product details, store locations, or timeframes. The system is designed to handle requests securely and provide clear feedback if a request cannot be processed due to errors or permission issues.

2.2 Step-by-Step Flow

1. Request Submission: A user initiates a request to view stock reservations.
2. Applying Filters: The system checks for any provided search criteria, such as a specific date range, product name, product code (SKU), or store location, and applies these to the search.
3. Data Retrieval: The system searches the inventory database using the applied filters to find matching reservation records.
4. Validation and Security Check: Throughout the process, the system verifies that the user is authorized to view this information and that the request format is correct.
5. Response Delivery:

* If successful, the system returns the list of matching reservations.

* If the request is invalid, unauthorized, or a system error occurs, the system returns a specific message explaining why the request could not be completed.

2.3 Key Concepts

- Stock Reservation: A record indicating that a specific quantity of a product has been set aside at a particular store location.
- Filtering: The ability to narrow down a large list of records by applying specific conditions (e.g., "show me only reservations for this store from last week").
- Authentication: The process of verifying the user's identity to ensure they are allowed to access the system.
- Authorization: The process of checking if an authenticated user has the specific permissions required to view sensitive inventory data.
- Error Handling: The system's way of providing meaningful feedback (such as "Forbidden" or "Bad Request") when something goes wrong, rather than simply failing silently.

2.4 Business Value

This feature improves inventory visibility and operational efficiency. By allowing staff to quickly filter and locate specific stock reservations, the business can:

* Reduce Errors: Quickly verify which products are held for specific orders or locations.

* Improve Customer Service: Provide accurate, real-time information about product availability and reservation status.

* Enhance Security: Ensure that sensitive inventory data is only accessible to authorized personnel, protecting business intelligence.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Stock Orders API feature provides a secure way for users to retrieve lists of stock orders within the Lumi ERP system. This feature is designed to support different views—such as Warehouse, Service Orders, and Work Orders—by filtering data based on the "source type" of the order. The system automatically ensures that users only see data belonging to their own company, maintaining strict data privacy.

1.2 Step-by-Step Flow

1. Authentication: The system verifies the user's identity. If the user is not logged in or authorized, the request is rejected.
2. Parameter Validation: The system checks the request for the required "source type" (e.g., warehouse or service order). If this information is missing or invalid, the request is rejected.
3. Data Retrieval: The system searches the database for stock orders that match the requested source type, automatically limiting the results to the user's specific company.
4. Sorting and Pagination: The system organizes the results based on the user's preferred sorting criteria (defaulting to the newest items first) and breaks the list into manageable pages to ensure fast performance.
5. Response: The system returns the requested list of orders to the user. If no orders match the criteria, an empty list is returned.

1.3 Key Concepts

- Source Type: A category label used to distinguish between different types of orders (e.g., Warehouse vs. Service Orders), allowing the interface to display the correct information on the appropriate tab.
- Pagination: A method of breaking large amounts of data into smaller, numbered pages to improve system speed and readability.
- Company Scoping: A security measure that automatically filters all database queries so that users only see records associated with their specific organization.
- Sorting: The ability to arrange the order list by specific criteria, such as the date the order was created. Note that some financial fields, like order amounts, cannot be used for sorting.

1.4 Business Value

This feature enables efficient inventory management by allowing users to quickly find and organize stock orders across different operational areas. By providing a standardized, secure, and paginated way to access this data, the API ensures that the user interface remains responsive and that sensitive company information remains protected.

It simplifies the user experience by allowing the application to dynamically switch between different order views using a single, reliable data source.

2. Data

2.1 Overview

The Stock Orders feature provides a way to retrieve and view lists of stock-related orders within the Lumi ERP system. It is designed to support different views (tabs) based on the origin of the order, such as warehouse stock, service orders, or work orders. The system automatically ensures that users only see data relevant to their own company, keeping information secure and organized.

2.2 Step-by-Step Flow

1. Security Check: The system identifies the user's company and automatically restricts the search to only show orders belonging to that specific company.
2. Categorization: The system applies a filter based on the "source type" (e.g., Warehouse, Service, or Work Order) to ensure the correct list is displayed for the selected tab.
3. Search: If a search term is provided, the system narrows down the results by looking for matching order numbers.
4. Sorting: The system organizes the results. By default, it shows the newest orders first. Note that some financial fields cannot be used for sorting.
5. Pagination: To keep the interface fast and readable, the system breaks the results into manageable pages (defaulting to 20 items per page) and calculates the total number of available records.
6. Delivery: The system returns the requested list of orders along with summary information about the total count and current page.

2.3 Key Concepts

- Source Type: A category label that determines which tab an order appears in, such as "Warehouse" or "Service Order."
- Company Scoping: An automatic security feature that ensures users only access data belonging to their own organization.
- Pagination: A method of displaying large amounts of data in smaller, easier-to-manage chunks rather than loading everything at once.
- Sorting Restrictions: Specific rules that prevent the system from organizing data by certain financial fields to maintain performance and data integrity.

2.4 Business Value

This feature enables efficient inventory and order management by providing a clean, searchable, and organized view of all stock-related activities. By automatically filtering data by company and order type, it reduces manual effort for staff, prevents unauthorized data access, and ensures that users can quickly locate the specific order information they need to keep operations running smoothly.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/purchase-returns

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a way for authorized users to retrieve a list of purchase returns within the Lumi ERP system. It is designed to be flexible, allowing users to search through their return records using specific filters, sorting preferences, and pagination to manage large volumes of data efficiently. The system automatically ensures that users only see data belonging to their own company based on their active login session.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to view purchase return records.
2. Parameter Processing: The system collects your search criteria (such as the specific warehouse, return type, or asset category) and your display preferences (such as how many items to show per page and how to sort the list). If no preferences are provided, it defaults to showing the most recently created returns first.
3. Data Retrieval: The system searches the database for records that match your criteria, ensuring the results are restricted to your company's data.
4. Delivery: The system returns the requested list of purchase returns. If no records match your search, it will return an empty list rather than an error.

1.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, manageable "pages" to improve performance and readability.
- Filtering: The ability to narrow down the list of returns based on specific criteria, such as whether an item is a fixed asset, the type of return, or the warehouse location.
- Sorting: The ability to organize the list by specific fields (like date) in either ascending or descending order.
- Session-Based Scoping: A security feature that automatically identifies which company the user belongs to, ensuring they can only access their own company's data without needing to manually specify a company ID.

1.4 Business Value

This feature empowers staff to quickly audit and manage return history without manual data entry or complex database queries. By providing robust filtering and sorting, users can instantly locate specific return transactions—such as identifying all returns from a particular warehouse or isolating fixed asset returns—which streamlines inventory reconciliation and improves financial reporting accuracy.

2. Data

2.1 Overview

The Purchase Returns feature provides a centralized way to view and track items that have been sent back to vendors. This tool allows your team to retrieve a list of all return transactions, filter them by their current status or specific date ranges, and see the underlying details of what was returned and which original purchase orders were affected.

2.2 Step-by-Step Flow

1. Filter and Search: The system receives your request to view returns, applying any filters you have selected, such as the return status (e.g., "Pending" or "Completed") or a specific timeframe.
2. Retrieve Return Records: The system gathers the relevant return records from the database, automatically sorting them so that the most recent returns appear at the top of your list.
3. Fetch Item Details: For the returns found, the system looks up the specific items included in those returns, such as the quantity and price of the products being sent back.
4. Link to Original Orders: The system identifies the original purchase orders associated with these returns and retrieves the order numbers, ensuring you have the necessary context to cross-reference the return with the initial purchase.
5. Consolidate Data: The system combines all this information into a clear, comprehensive view for you to review.

2.3 Key Concepts

- Purchase Return: A record of goods sent back to a vendor, including the date of the return, the total value, and the current processing status.
- Return Items: The specific breakdown of products within a return, detailing exactly what was sent back and at what cost.
- Purchase Order Context: The link between a return and the original purchase, allowing you to see the specific order number that triggered the return process.
- Filtering: The ability to narrow down your view by date or status, helping you focus on specific batches of returns rather than searching through the entire history.

2.4 Business Value

This feature improves inventory accuracy and financial transparency by providing a clear audit trail of all vendor returns. By linking returns directly to original purchase orders, your team can quickly resolve discrepancies, track vendor performance, and ensure that financial records—such as credits or refunds—are correctly aligned with the physical movement of inventory.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/purchase_order

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for users to view a list of all purchase orders associated with their specific company. By requesting this information, the system automatically identifies the user's company and retrieves the relevant order history, ensuring that users only see data they are authorized to access.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in. If the user is not authenticated, the request is denied.
2. Company Identification: The system identifies the user's company based on their account profile.
3. Company Validation: The system confirms that the identified company exists in the database.
4. Data Retrieval: The system searches the database for all purchase orders linked to that specific company.
5. Display Results: The system returns the list of purchase orders, including key details such as the order ID, status, and the date the order was created.

1.3 Key Concepts

- Authentication: The process of verifying the user's identity to ensure they have a valid, active session before accessing company data.
- Purchase Order: A formal document representing a request to purchase goods or services, tracked within the system with a unique ID and status.
- Data Privacy: By automatically linking the request to the user's company ID, the system prevents users from accidentally or intentionally accessing purchase orders belonging to other companies.

1.4 Business Value

This feature streamlines inventory and procurement management by providing immediate visibility into company spending and order status. It reduces manual administrative work by allowing users to pull up-to-date order lists instantly, while maintaining strict security standards by ensuring that sensitive procurement data remains isolated to the correct organization.

2. Data

2.1 Overview

This feature allows the system to process and record new purchase orders for your company. It acts as a gatekeeper, ensuring that every order is valid, authorized, and supported by available inventory before it is officially saved in the system.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and has the necessary permissions to create a purchase order.
2. Validation: The system checks the incoming order details to ensure all required information is present and correctly formatted.
3. Product Verification: The system confirms that every product requested in the order actually exists in the inventory database.
4. Stock Availability Check: The system verifies that there is enough stock on hand to fulfill the requested quantities for each item.
5. Order Creation: If all checks pass, the system creates a new purchase order record, links the specific items to that order, and saves the transaction.
6. Confirmation: The system returns the newly created order details to the user. If any step fails (e.g., insufficient stock or missing permissions), the system provides an appropriate error message to explain why the order could not be processed.

2.3 Key Concepts

- Authentication: The process of confirming the user's identity and ensuring they have the right to perform the requested action.
- Validation: A quality-control step that ensures the data provided is complete and follows the required rules.
- Inventory Integrity: The practice of checking product existence and stock levels before finalizing an order to prevent overselling or errors.
- Transaction: A "all-or-nothing" operation that ensures the purchase order and its individual items are saved together correctly, preventing partial or corrupted data.

2.4 Business Value

This feature automates the order entry process, reducing manual data entry errors and ensuring that your company only accepts orders that can actually be fulfilled. By validating stock levels and permissions in real-time, the system protects your inventory accuracy and provides immediate feedback to users, leading to a more reliable and efficient supply chain workflow.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-outgoings

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Stock Outgoings" API feature allows users to retrieve a list of records representing items leaving company inventory. This tool is designed to help staff track outgoing stock movements by providing flexible search, filtering, and sorting capabilities, all while ensuring that users only see data relevant to their specific company.

1.2 Step-by-Step Flow

1. Session Verification: The system automatically identifies the user's company based on their active login session, ensuring data privacy and isolation.
2. Parameter Processing: The system collects your search criteria, such as the desired page number, status, and date range. It validates these inputs to ensure, for example, that a "start date" does not occur after an "end date."
3. Data Filtering: The system applies your filters to the database. It restricts results to your company and narrows them down based on the status (e.g., draft, confirmed, approved, or cancelled) and the specific timeframe requested.
4. Sorting: The system organizes the results. You can sort by various fields, such as the date created, the user who initiated the outgoing stock, or the source location.
5. Pagination: To keep performance fast and manageable, the system displays results in fixed batches of 20 records at a time.
6. Result Delivery: The system returns the requested list of stock outgoing records. If no records match your criteria, it returns an empty list rather than an error.

1.3 Key Concepts

- Company Isolation: A security measure that ensures users can only access stock records belonging to their own organization.
- Status Filtering: The ability to view records based on their current lifecycle stage, such as "Draft" (in progress) or "Confirmed" (finalized).
- Pagination: A method of breaking large amounts of data into smaller, readable pages (fixed at 20 items per page) to improve system speed.
- Date Range Validation: A safeguard that prevents errors by ensuring the "from" date is always chronologically before the "to" date.
- Sorting Logic: The ability to order results by specific attributes, such as the name of the person who created the record or the name of the source location, rather than just internal ID numbers.

1.4 Business Value

This feature provides operational transparency for inventory management. By allowing staff to quickly filter and sort through outgoing stock, the business can:

* Improve Accuracy: Easily audit outgoing stock by searching for specific statuses or date ranges.

* Enhance Productivity: Quickly locate specific outgoing shipments without manually scrolling through large datasets.

* Maintain Security: Automatically enforce data boundaries so that sensitive inventory information is only visible to authorized company members.

2. Data

2.1 Overview

The "Stock Outgoings" feature provides a way for users to retrieve a list of all inventory outgoing records associated with their company. This tool is designed to help warehouse managers and inventory staff easily track, filter, and organize outgoing stock movements. The system ensures data security by automatically scoping results to the user's company and includes built-in validation to prevent errors when searching or sorting.

2.2 Step-by-Step Flow

1. Request Initiation: The user requests a list of stock outgoings. The system automatically identifies the user's company from their active session, ensuring they only see relevant data.
2. Validation: The system checks the request parameters. If the status provided is invalid (e.g., not one of the recognized statuses) or if the date range is illogical (e.g., the "from" date is after the "to" date), the request is rejected.
3. Filtering: The system applies any requested filters, such as specific stock statuses (draft, confirmed, approved, or cancelled), specific source locations, or a specific date range.
4. Sorting: The system organizes the results based on the user's preference, such as by date, the name of the source location, or the name of the user who created the record. If no preference is provided, it defaults to showing the most recent records first.
5. Pagination: To keep the interface fast and readable, the system returns results in fixed batches of 20 items per page.
6. Data Delivery: The system returns the final list of records. If no records match the criteria, the system returns an empty list rather than an error.

2.3 Key Concepts

- Company Scoping: A security measure that ensures users only access data belonging to their specific organization, preventing data leakage between different companies.
- Status Filtering: Allows users to narrow down results by the lifecycle stage of the outgoing stock (e.g., seeing only "approved" items).
- Pagination: A method of breaking large datasets into smaller, manageable chunks (20 items at a time) to improve system performance and user experience.
- Data Validation: Automated checks that ensure search criteria are logical and formatted correctly before the system attempts to process them.

2.4 Business Value

This feature improves operational efficiency by allowing staff to quickly locate specific stock movements without manually scanning through entire databases. By providing flexible filtering and sorting, it supports better inventory oversight and reporting. Furthermore, the built-in validation and automatic company scoping reduce the risk of human error and unauthorized data access, ensuring that inventory records remain accurate and secure.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/franchise-purchase-orders/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve the high-level summary (the "header") of a specific franchise purchase order. By providing a unique order ID, the system will return key financial and status information, such as the order type, total costs, and current status. This information is designed to populate the main details page for a purchase order, keeping the data lightweight by excluding the individual line items, which are handled separately.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided order ID is in the correct format. If the format is incorrect, it returns an error.
2. Security Check: The system attempts to locate the purchase order in the database. It automatically restricts the search to the company associated with the currently logged-in user, ensuring that users can only access their own company's data.
3. Existence Check: If the order cannot be found—either because it doesn't exist or because it belongs to a different company—the system returns a "not found" error. This approach protects sensitive data by not revealing whether a record exists in another company's account.
4. Data Retrieval: If the order is found, the system returns the header details, including the order type, status, date, and all relevant financial totals (subtotal, tax, discount, shipping, and grand total).

1.3 Key Concepts

- Header Information: The core summary of a purchase order (e.g., totals and status) that remains constant regardless of how many individual items are in the order.
- Data Isolation: A security practice where the system automatically filters data based on the user's company, preventing unauthorized access to other companies' information.
- ID Enumeration Protection: A security measure where the system returns a "not found" error instead of an "access denied" error, preventing outsiders from guessing or confirming the existence of records they shouldn't see.
- Order Type: A label that tells the system which layout or interface to display, allowing one endpoint to support different types of purchase orders.

1.4 Business Value

- Improved Performance: By separating the order header from the individual line items, the system can load the main order summary quickly and allow the line-item table to be managed independently (e.g., scrolling through pages of items without reloading the entire order).
- Enhanced Security: The automatic scoping of data by company ensures that franchise data remains private and secure, meeting compliance requirements for multi-tenant environments.
- Simplified Integration: Providing a single, consistent endpoint for all purchase order types reduces complexity for the front-end team, as they can rely on the `order_type` field to determine how to display the information to the user.

2. Data

2.1 Overview

This feature provides a way for the system to retrieve the high-level details of a specific franchise purchase order. When a user requests a purchase order by its unique ID, the system fetches the "header" information—such as the order status, date, and financial totals—to display on the order details page. This endpoint is designed to be secure and efficient, ensuring users can only access data belonging to their own company.

2.2 Step-by-Step Flow

1. Request: The system receives a request for a specific purchase order using its unique ID.
2. Validation: The system checks if the provided ID is in the correct format. If the format is invalid, the request is rejected.
3. Security Check: The system identifies the company associated with the logged-in user and attempts to find the requested order only within that company's records.
4. Retrieval: If the order exists and belongs to the user's company, the system gathers the order details (including subtotal, tax, discounts, shipping, and grand total).
5. Response: The system returns the order information to the user. If the order cannot be found (or if it belongs to a different company), the system returns a "not found" error to protect data privacy.

2.3 Key Concepts

- Header Information: The core summary of the purchase order, including financial totals and status, which is kept separate from the individual line items to improve performance.
- Multi-tenancy: A security practice where the system automatically filters data based on the user's company, ensuring that one franchise cannot view the purchase orders of another.
-

Data Privacy: By returning a "not found" error instead of an "access denied" error when a user requests an order they don't own, the system prevents unauthorized users from confirming the existence of other companies' records.

- Order Type: A label on the order record that tells the user interface which layout or template to use when displaying the details.

2.4 Business Value

- Improved Performance: By separating the order "header" (totals and status) from the "line items," the system can load the main order details quickly without needing to process large lists of individual products at the same time.
- Enhanced Security: The automatic scoping of data by company ensures that sensitive financial information remains private and accessible only to authorized personnel.
- Consistent User Experience: Because this single endpoint handles different types of purchase orders, the front-end application can dynamically adjust its display based on the order type, providing a seamless experience for the user.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/franchise-purchase-orders/:id/items

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to view the specific list of products (line items) associated with a single franchise purchase order. By providing the unique ID of a purchase order, users can retrieve a detailed breakdown of the items included in that order. The system automatically ensures that users can only view orders that belong to their own company, maintaining data security and privacy.

1.2 Step-by-Step Flow

1. Verification: The system checks if the requested purchase order exists and confirms that it belongs to the company associated with the user currently logged in. If the order cannot be found or belongs to a different company, the system returns an error.
2. Data Retrieval: Once access is confirmed, the system fetches the list of items for that specific order. The items are retrieved in the order they were originally added.
3. Pagination: To keep the information manageable, the system breaks the list into smaller "pages." The user can specify which page they want to view and how many items should appear on each page.
4. Response: The system returns the requested items, the total number of items in the order, and the current page information to the user.

1.3 Key Concepts

- Franchise Purchase Order: The parent document that contains a collection of individual product line items.
- Pagination: A method of splitting a large list of items into smaller, easier-to-read segments (pages) to improve performance and readability.
- Access Scoping: A security measure that automatically filters data so that users only see information relevant to their specific organization.
- Insertion Order: The default way items are displayed, showing them in the sequence they were originally added to the order.

1.4 Business Value

This feature enables franchise managers and staff to easily audit and review the contents of specific purchase orders. By supporting pagination, the system remains fast and responsive even when dealing with large orders containing many line items. Furthermore, the built-in security checks ensure that sensitive procurement data remains protected, as users are restricted to viewing only the purchase orders authorized for their company.

2. Data

2.1 Overview

This feature provides a way to retrieve a list of all products associated with a specific franchise purchase order. It is designed to be secure and efficient, ensuring that users can only view items for orders that belong to their own company. The system automatically handles large lists by breaking them into manageable pages.

2.2 Step-by-Step Flow

1. Verification: The system first checks if the requested purchase order exists and confirms that it belongs to the company associated with the user making the request. If the order cannot be found or belongs to a different company, the request is denied.
2. Data Retrieval: Once the order is verified, the system fetches the list of items linked to that specific order. These items are returned in the order they were originally added.
3. Pagination: To keep performance high, the system retrieves only a specific "page" of items at a time, based on the limits set by the user.
4. Metadata Calculation: The system calculates the total number of items in the order to help the user interface display accurate pagination information (such as total pages or item counts).
5. Response: The system returns the requested page of items along with the total count and pagination details.

2.3 Key Concepts

- Data Isolation: A security measure that ensures users can only access information belonging to their own organization, preventing unauthorized access to other companies' data.
- Pagination: A method of splitting a large list of items into smaller, manageable chunks (pages) to improve system speed and user experience.
- Parent-Child Relationship: The structure where "Items" are dependent on a "Purchase Order." You cannot view the items without first validating the existence of the parent order.
- Insertion Order: The items are displayed in the sequence they were created, ensuring a consistent view of the order history.

2.4 Business Value

This feature enables franchise managers and staff to accurately review the contents of purchase orders. By enforcing strict data isolation, it protects sensitive business information. Furthermore, the use of pagination ensures that even very large purchase orders can be viewed quickly and reliably without slowing down the application.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/stock-returns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to initiate a "Stock Return" process within the Lumi ERP system. When a store needs to return items to a central warehouse, this tool records the movement, linking the specific store, the destination warehouse, and the internal supplier involved. It ensures that all returns are tracked, validated, and stored securely in the system.

1.2 Step-by-Step Flow

1. Verification: The system checks if the user is logged in and has the necessary permissions to create a stock return.
2. Validation: The system reviews the request to ensure all required information—specifically the store ID, warehouse ID, and internal supplier ID—is provided.
3. Processing: If the information is valid, the system creates a new record, assigns it a unique identifier, sets the status to "Pending," and logs the time and the user who initiated the request.
4. Confirmation: The system saves the record to the database and returns a confirmation message containing the full details of the newly created stock return.

1.3 Key Concepts

- Stock Return: A formal record indicating that inventory is being moved from a retail store back to a central warehouse or supplier.
- Payload: The specific set of information (store, warehouse, and supplier details) that the user must provide to initiate the return.
- Status (Pending): The initial state of a new return record, indicating that the request has been successfully logged but has not yet been processed or completed.
- Authentication/Authorization: Security checks that ensure only verified staff members with the correct job roles can create or modify return records.

1.4 Business Value

- Inventory Accuracy: By formalizing the return process, the business maintains a clear audit trail of where inventory is located, reducing discrepancies between store and warehouse stock levels.
- Operational Efficiency: Automating the creation of these records removes manual paperwork, allowing store staff to quickly initiate returns and warehouse teams to receive them with clear, digital documentation.
- Accountability: Every return is linked to the user who created it and the specific entities involved, ensuring transparency and easier troubleshooting if a shipment is lost or misdirected.

2. Data

2.1 Overview

The "Stock Returns" feature allows the Lumi ERP system to formally record the movement of inventory from a retail store back to a central warehouse. This process ensures that when stock is returned, the system accurately tracks where the items originated, where they are being sent, and which internal supplier is associated with the return. This feature provides a reliable digital audit trail for inventory management.

2.2 Step-by-Step Flow

1. Request Submission: A user initiates a request to create a new stock return record, providing the store, warehouse, and supplier details.
2. Validation: The system checks that the request contains all necessary information and that the store, warehouse, and supplier mentioned actually exist in the system.
3. Verification: If any information is missing or if the referenced locations/suppliers cannot be found, the system rejects the request to prevent data errors.
4. Record Creation: Once validated, the system creates a new, permanent record of the return, assigning it a unique ID and a timestamp.
5. Confirmation: The system returns the finalized record details to the user to confirm that the stock return has been successfully logged.

2.3 Key Concepts

- Stock Return: A formal record documenting the transfer of inventory from a store back to a warehouse.
- Referential Integrity: A safety check that ensures the system only accepts returns involving valid, existing stores, warehouses, and suppliers.
- Payload: The collection of data sent by the user to the system, containing the specific details of the return.
- Persistence: The process of saving the return information into the system's permanent database so it can be retrieved or audited later.

2.4 Business Value

- Inventory Accuracy: By requiring valid references for every return, the system prevents "ghost" inventory and ensures that stock levels remain accurate across all locations.
- Operational Accountability: Every return is linked to a specific user and internal supplier, providing clear visibility into who initiated the return and which part of the supply chain is involved.
-

Audit Readiness: The automated creation of timestamps and unique identifiers ensures that the business maintains a clean, reliable history of inventory movements for reporting and reconciliation purposes.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/stock-opname

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Create Stock Opname" feature provides a reliable way to record physical inventory counts in the Lumi ERP system. When a user submits a stock count, the system automatically compares the physical count against the current system records, calculates any discrepancies (variances), and saves the entire document as a single, unified record.

1.2 Step-by-Step Flow

1. Submission: The user sends a request containing the main stock opname details (such as the store location and date) and a list of individual items counted.
2. Duplicate Check: The system verifies that this specific request has not been processed previously to prevent accidental duplicate entries.
3. Transaction Start: The system initiates a secure "all-or-nothing" process. This ensures that either the entire document and all its items are saved correctly, or nothing is saved at all if an error occurs.
4. Header Creation: The system creates the main stock opname record, automatically generating a unique reference code and timestamps.
5. Item Processing: For every item in the list, the system:

* Retrieves the current system quantity and average cost for that product.

* Calculates the difference between the physical count and the system quantity.

* Determines the financial adjustment amount based on that difference.

* Saves the item details along with these calculated values.

6. Completion: Once all items are processed, the transaction is finalized, and the system confirms the successful creation of the record.

1.3 Key Concepts

– Stock Opname: A formal record of a physical inventory count used to reconcile actual stock levels with system records.
– Transaction: A safety mechanism that treats the entire submission as one unit; if any part of the data is invalid, the system rolls back the entire process to prevent partial or corrupted data.
– Variance: The difference between the quantity physically counted by the user and the quantity currently recorded in the system.
–

Adjustment Amount: The financial impact of the inventory discrepancy, calculated by multiplying the variance by the product's average cost.

– Duplicate Prevention: A safeguard that uses a unique request identifier to ensure the same inventory count cannot be submitted twice.

1.4 Business Value

– Data Integrity: By using a single transaction, the system guarantees that inventory records remain accurate and consistent, preventing "half-saved" documents.

– Automated Reconciliation: The system removes the manual burden of calculating variances and financial adjustments, reducing human error and saving time.

– Audit Readiness: Every stock opname is assigned a unique reference code and timestamp, providing a clear, traceable history of inventory adjustments for reporting and auditing purposes.

– Operational Reliability: Built-in checks for duplicates and invalid data ensure that the inventory database remains clean and trustworthy.

2. LOGIC

2.1 Overview

The "Create Stock Opname" feature provides a reliable way for the system to record physical inventory counts. When a user submits a stock count, this feature captures the details of the inventory check, compares the counted quantities against the system's current records, and calculates any discrepancies (variances) in both quantity and value. This ensures that the inventory records remain accurate and synchronized with the physical stock on hand.

2.2 Step-by-Step Flow

1. Validation: The system first checks that the request is unique to prevent accidental duplicate entries.
2. Record Creation: The system creates a new "Stock Opname" header record, automatically assigning it a unique reference code and linking it to the current user and company.
3. Item Processing: For every product included in the count, the system performs the following:

* Checks for duplicate product entries within the same count.

* Retrieves the current system quantity and average cost for that product.

* Calculates the difference between the physical count and the system quantity.

* Calculates the financial impact (adjustment amount) based on the variance.

4.

Finalization: All records are saved together. If any part of the process fails, the system cancels the entire operation to ensure no partial or incorrect data is saved.

2.3 Key Concepts

- Stock Opname: A formal record of a physical inventory count performed at a specific store on a specific date.
- Atomicity (Transaction): A "all-or-nothing" approach where the system ensures that either the entire inventory count is saved successfully, or nothing is saved at all, preventing data errors.
- Variance: The difference between what the system thinks is in stock and what was actually counted.
- Snapshot: A record of the system's state (quantity and cost) at the exact moment the count was performed, which is preserved for historical auditing.
- Request Uniqueness: A safety mechanism that prevents the same inventory count from being processed twice if a network error occurs during submission.

2.4 Business Value

This feature provides a robust audit trail for inventory management. By automatically calculating variances and financial adjustments, it reduces manual calculation errors and saves time for warehouse or store staff. Because the system captures a "snapshot" of costs and quantities at the time of the count, management can easily identify discrepancies, investigate stock shrinkage, and maintain high levels of inventory accuracy for financial reporting.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/franchise-purchase-orders/:id/confirm

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized users to finalize a franchise purchase order by moving it from a "draft" state to a "store confirmed" state. This action is a critical step in the procurement workflow, signaling that the order is ready for the next stage of processing. The system performs several security and status checks to ensure that only the correct users can modify valid, existing orders.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided order identifier is formatted correctly.
2. Authentication & Authorization: The system verifies that the user is logged in and holds an "admin" or "manager" role.
3. Order Retrieval: The system searches for the specific purchase order. It ensures the order exists and belongs to the user's company.
4. Status Check: The system confirms the order is currently in "draft" status. If the order has already been processed or is in a different state, the request is rejected to prevent accidental changes.
5. Update: If all checks pass, the system updates the order status to "store confirmed," records the current time, and saves the changes.

1.3 Key Concepts

- Franchise Purchase Order: A document used by a franchise location to request goods or services from the parent company.
- Workflow State: The current stage of an order in its lifecycle (e.g., "draft" vs. "store confirmed"). This ensures orders follow a logical progression.
- Authorization: A security measure that restricts the ability to confirm orders to specific roles, such as managers or administrators, preventing unauthorized staff from making changes.
- Data Integrity: The process of verifying that an order exists and belongs to the correct company before allowing any modifications, ensuring that users cannot accidentally or maliciously alter orders they do not own.

1.4 Business Value

This feature streamlines the procurement process by providing a clear, controlled transition for purchase orders. By enforcing role-based access and status validation, it reduces the risk of human error, prevents unauthorized modifications to financial documents, and ensures that only valid, "draft" orders can be moved into the confirmation pipeline. This creates a reliable audit trail and improves operational efficiency for franchise management.

2. Data

2.1 Overview

This feature allows authorized users to finalize a franchise purchase order by moving it from a "draft" state to a "store confirmed" state. This process ensures that only the correct personnel can confirm orders and that orders can only be confirmed if they are currently in the appropriate draft stage.

2.2 Step-by-Step Flow

1. Authorization Check: The system verifies that the user attempting the action has the required "admin" or "manager" role.
2. Order Retrieval: The system searches for the specific purchase order. It confirms that the order exists and that it belongs to the same company as the user making the request.
3. State Validation: The system checks the current status of the order. If the order is not in the "draft" state, the request is rejected to prevent accidental or duplicate confirmations.
4. Status Update: If all checks pass, the system updates the order status to "store confirmed" and records the time of the update.

2.3 Key Concepts

- Authorization: A security gate that restricts access to specific roles (Admin or Manager) to ensure only authorized staff can finalize orders.
- State Transition: The process of moving an order from one phase (Draft) to another (Store Confirmed). The system enforces this to maintain data integrity.
- Data Ownership: A security measure that ensures a user can only view or modify purchase orders that belong to their specific company.
- Atomic Update: A safety mechanism that ensures the order status is only changed if it is currently in the expected "draft" state, preventing conflicts if multiple users try to update the same order simultaneously.

2.4 Business Value

This feature provides a controlled, secure workflow for franchise procurement. By enforcing role-based access and strict state transitions, it reduces the risk of unauthorized order modifications and prevents errors caused by confirming orders that are not ready or have already been processed. This ensures accurate inventory tracking and reliable communication between the franchise and the central system.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/franchise-purchase-orders/:id/receive

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows authorized staff (Admins or Managers) to confirm the receipt of goods for a franchise purchase order. When a franchise receives a shipment, this process updates the order status to "received" and automatically records the incoming stock into the inventory system for each item listed.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and holds the necessary administrative or managerial permissions to perform this action.
2. Order Verification: The system locates the specific purchase order and ensures it is currently in the "placed" state. If the order has already been processed or does not exist, the request is rejected.
3. Input Validation: The system checks the provided list of items to ensure there are no duplicate entries and that the quantity being received does not exceed the quantity originally ordered.
4. Inventory Update: The system performs a secure, all-or-nothing update. It records the received quantity for each item and creates an official inventory movement log to reflect the new stock levels.
5. Finalization: Once all items are processed successfully, the purchase order status is updated to "store_received," and the system confirms the successful completion of the transaction.

1.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures all parts of the update (updating the order status and recording inventory movements) happen together. If any part of the process fails, the entire operation is canceled to prevent data errors.
- Franchise Workflow State: A status tracker that ensures purchase orders move through the system in the correct sequence (e.g., an order must be "placed" before it can be "received").
- Inventory Movement: A digital record created whenever stock levels change, providing an audit trail of how and when products were added to the franchise's inventory.

1.4 Business Value

This feature streamlines the franchise supply chain by automating the transition from "ordered" to "received." By integrating inventory updates directly into the receipt process, it eliminates manual data entry, reduces the risk of human error, and ensures that franchise stock levels are always accurate and up-to-date immediately upon delivery.

2. Data

2.1 Overview

This feature allows franchise staff to officially "receive" a purchase order that has been placed. When a user marks an order as received, the system updates the order's status and automatically records the incoming stock into the franchise's inventory records. This ensures that the digital inventory levels accurately reflect the physical goods that have arrived at the store.

2.2 Step-by-Step Flow

1. Validation: The system verifies that the user has the correct permissions and that the purchase order exists and belongs to their franchise.
2. Status Check: The system confirms the order is currently in the "placed" state. If the order has already been processed or is in a different state, the request is rejected to prevent duplicate entries.
3. Quantity Verification: The system checks that the received quantities do not exceed the amounts originally ordered.
4. Order Update: The system updates the purchase order status to "store_received."
5. Inventory Recording: For every item in the order, the system updates the received quantity and creates an inventory movement record, which increases the franchise's stock levels for those specific products.
6. Finalization: These updates happen as a single, unified action; if any part of the process fails, none of the changes are saved, ensuring data consistency.

2.3 Key Concepts

- Purchase Order: A formal request for goods sent by a franchise to a supplier.
- Inventory Movement: A digital log entry that tracks changes in stock levels (in this case, an increase due to a delivery).
- Atomic Transaction: A safety mechanism that ensures all parts of an update (status change and inventory recording) succeed together or fail together, preventing partial or incorrect data.
- Workflow State: The current stage of an order (e.g., "placed" vs. "store_received"), which dictates what actions can be performed on it.

2.4 Business Value

- Accuracy: By automating the creation of inventory movements, the system eliminates manual data entry errors, ensuring that store inventory levels are always up-to-date.
- Operational Control: The system prevents common mistakes, such as receiving more items than were ordered or processing the same delivery twice.
-

Auditability: Every receipt of goods is automatically logged, providing a clear history of when and how much stock was added to the franchise's inventory.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/franchise-purchase-orders/:id/cancel

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature allows authorized users to cancel a franchise purchase order within the Lumi ERP system. By triggering this action, an order that is currently in the early stages of the procurement process can be officially marked as "cancelled," ensuring that inventory records accurately reflect the status of the request.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided order ID is formatted correctly.
2. Authorization: The system verifies that the person making the request is logged in and holds an "admin" or "manager" role.
3. Retrieval: The system searches for the specific purchase order in the database.
4. Ownership Check: The system confirms that the order belongs to the user's company. If the order cannot be found or belongs to a different company, the request is denied.
5. Status Check: The system ensures the order is in a state that allows for cancellation (specifically, it must be in "draft" or "store_confirmed" status). If the order has already progressed further, the cancellation is blocked.
6. Finalization: If all checks pass, the system updates the order status to "cancelled," records the time of the update, and confirms the change.

1.3 Key Concepts

- Franchise Purchase Order: A formal request for goods or services initiated by a franchise location.
- Workflow State: The current stage of an order (e.g., draft, confirmed, or cancelled). This ensures orders can only be modified when appropriate.
- Authorization: A security measure that restricts the ability to cancel orders to specific management roles to prevent unauthorized changes.
- Ownership Validation: A safeguard that ensures users can only interact with purchase orders associated with their own company.

1.4 Business Value

This feature provides operational flexibility by allowing managers to correct mistakes or respond to changes in demand by cancelling orders that have not yet been fully processed. It maintains data integrity by preventing the cancellation of orders that are already too far along in the fulfillment cycle, while ensuring that only authorized personnel can modify financial or inventory-related documents.

2. Data

2.1 Overview

This feature allows authorized users to cancel a franchise purchase order within the Lumi ERP system. The system ensures that only orders in specific early stages (Draft or Store Confirmed) can be cancelled, preventing the cancellation of orders that have already progressed too far in the fulfillment process.

2.2 Step-by-Step Flow

1. Verification: The system confirms the user has the necessary permissions and that the requested order exists and belongs to their company.
2. Status Check: The system checks the current status of the order.
3. Validation: If the order is in a "Draft" or "Store Confirmed" state, the system proceeds. If the order is in any other state, the cancellation is blocked.
4. Cancellation: The system updates the order status to "Cancelled" and records the time of the update.

2.3 Key Concepts

- Workflow State: The current stage of an order in its lifecycle (e.g., Draft, Store Confirmed, or Cancelled).
- Transition Validation: A safety check that ensures an order only moves to a "Cancelled" state if it is logically appropriate to do so.
- Data Ownership: A security measure that ensures users can only view or modify orders associated with their specific company.

2.4 Business Value

- Operational Control: Prevents accidental or unauthorized cancellation of orders that are already being processed or shipped.
- Data Integrity: Ensures that order statuses remain accurate and consistent throughout the procurement lifecycle.
- Security: Protects sensitive company data by enforcing strict access rules, ensuring users can only manage orders within their own organization.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/discrepancy-stocks

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure and reliable way for users to create "Discrepancy Stock" reports. These reports allow staff to record the actual quantities of products counted at a specific store location. The system is designed to ensure data integrity by validating all entries before saving and preventing duplicate reports if a user accidentally submits the same form twice.

1.2 Step-by-Step Flow

1. Duplicate Check: The system checks if the report has already been submitted using a unique request identifier. If it has, the system returns the existing report instead of creating a new one.
2. Security & Data Validation: The system verifies that the store belongs to the user's company. It also ensures the report contains at least one item, all products are valid, no product is listed twice, and all quantities are greater than zero.
3. Report Creation: Once validated, the system generates a unique reference code for the report and saves the header information along with all product lines.
4. Atomic Saving: The report and its items are saved as a single "all-or-nothing" transaction. This ensures that if any part of the save fails, the entire report is discarded, preventing incomplete or corrupted data.
5. Confirmation: Upon success, the system returns the finalized report details, including the generated reference code, so the user can immediately view or track the new document.

1.3 Key Concepts

- Idempotency: A safety mechanism that ensures submitting the same request multiple times does not result in duplicate reports; it simply returns the original result.
- Atomic Transaction: A "save all or nothing" approach that ensures a report is only created if every single line item is successfully processed.
- Reference Code: A unique, system-generated identifier (formatted as DISC/StoreCode/Sequence) used to track and display the report in the system.
- Draft State: All new reports are automatically set to a "draft" status, allowing for further review or action before they are finalized.

1.4 Business Value

- Data Accuracy: By validating product IDs, quantities, and store ownership at the point of entry, the system prevents human error and unauthorized reporting.
-

Operational Reliability: The "all-or-nothing" saving process prevents partial data entries, ensuring that inventory records remain consistent and trustworthy.

- User Experience: The idempotency feature protects users from accidental double-submissions (e.g., clicking "Submit" twice due to a slow connection), providing a smoother and more predictable workflow.
- Security: By automatically assigning company and user information based on the active session, the system prevents users from accidentally or intentionally filing reports for the wrong location or organization.

2. Data

2.1 Overview

This feature provides a secure and reliable way for users to submit "Discrepancy Stock" reports. These reports allow staff to record differences between expected and actual inventory counts at a specific store. The system is designed to ensure data integrity by validating all inputs, preventing duplicate submissions, and ensuring that reports are saved completely or not at all.

2.2 Step-by-Step Flow

1. Validation: The system checks that the store mentioned in the report belongs to the user's company. It also verifies that the report contains at least one item, that all products are valid, that no product is listed twice, and that all quantities are greater than zero.
2. Duplicate Prevention: The system checks if a report with the same unique request ID has already been submitted. If it has, the system returns the existing report instead of creating a duplicate.
3. Report Preparation: The system automatically assigns a unique reference code to the report (formatted as `DISC/store-code/sequence`), sets the status to "draft," and records the user who created it and the time of creation.
4. Atomic Saving: The system saves the report header and all individual product lines together in a single operation. This ensures that if any part of the process fails, the entire report is rolled back, preventing incomplete or "half-saved" data.
5. Confirmation: Once successfully saved, the system returns the full details of the new report, including the generated reference code, so the user can immediately view or manage the document.

2.3 Key Concepts

- Idempotency: A safety mechanism that ensures if a user accidentally submits the same form twice (e.g., by clicking "submit" multiple times), the system recognizes it as the same request and does not create duplicate reports.
-

Atomic Transaction: A "all-or-nothing" approach to saving data. It guarantees that the report header and its associated product lines are saved as a single unit, preventing data corruption.

- Server-Side Ownership: To maintain security and consistency, the system ignores certain data sent by the user (like the status or company ID) and instead uses verified information from the user's active session.
- Draft State: All new reports are automatically initialized as "drafts," allowing for further review or adjustments before they are finalized or processed.

2.4 Business Value

This feature streamlines inventory management by providing a standardized, error-proof method for recording stock discrepancies. By automating the reference numbering and enforcing strict validation, it reduces manual data entry errors and ensures that inventory records remain accurate and auditable. The built-in duplicate protection and atomic saving provide a robust experience for store operators, ensuring that their work is reliably captured without the risk of system-side data inconsistencies.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-transfers/product-lookup?{search}&{pagination}

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a search tool for the Stock Transfer form. When a user begins typing a product name, SKU, or code, this tool instantly finds matching items and retrieves their current inventory levels. By providing the source and destination locations, the system automatically calculates how much stock is available at both ends and the average cost of the item, allowing the user to fill out transfer details quickly and accurately.

1.2 Step-by-Step Flow

1. Validation: The system checks that a "source location" has been selected. If this is missing, the search cannot proceed, as the system needs to know where the stock is coming from to provide accurate data.
2. Search: The system filters the product database based on the text entered by the user (matching against SKU, product code, or name).
3. Data Retrieval: For every matching product found, the system looks up the specific inventory records for the chosen source location and (if provided) the destination location.
4. Result Compilation: The system bundles the product details with its current stock levels at both locations and the average unit cost.
5. Display: The results are returned to the user in a paginated list (30 items at a time) to ensure the interface remains fast and easy to navigate.

1.3 Key Concepts

- Source Location: The specific warehouse or storage area from which items are being moved; this is required to determine available stock and costs.
- Destination Location: The optional target warehouse where items are being sent; providing this allows the system to show current stock levels at the receiving end.
- Pagination: A method of breaking large lists of products into smaller, manageable pages to improve system performance and user experience.
- Inventory Metrics: The specific data points returned for each product, including quantity on hand at the source, quantity on hand at the destination, and the average cost of the item.

1.4 Business Value

This feature streamlines the stock transfer process by eliminating manual data entry. Instead of looking up stock levels in a separate window, users get all the necessary information—availability and costs—directly within the transfer form as they search. This reduces errors, saves time, and ensures that users have real-time visibility into inventory levels before finalizing a transfer.

2. Data

2.1 Overview

This feature provides a search tool for the Stock Transfer form. When a user begins typing a product name, SKU, or code, the system instantly retrieves matching products. Crucially, it doesn't just find the product; it also pulls in real-time inventory data for both the source and destination locations. This allows the form to automatically populate necessary details—such as current stock levels and unit costs—in a single step, eliminating the need for the user to perform additional lookups.

2.2 Step-by-Step Flow

1. Validation: The system checks that a "source location" has been provided. If this is missing, the request is rejected, as the system cannot calculate stock levels without knowing where the items are coming from.
2. Search: The system searches the product database for items that match the text entered by the user (checking against SKU, product code, or name).
3. Data Gathering: For every matching product, the system retrieves the inventory records for both the source and destination locations.
4. Formatting: The system compiles the results, pairing each product with its specific stock quantities and the average unit cost from the source location.
5. Pagination: The results are returned in manageable "pages" (defaulting to 30 items at a time) to ensure the system remains fast and responsive, even if the company has thousands of products.

2.3 Key Concepts

- Source Location: The specific warehouse or storage area from which items are being moved; this is required to calculate available stock and costs.
- Destination Location: The target warehouse where items are being sent; this is used to show the current stock level at the receiving end.
- Pagination: A method of breaking a large list of results into smaller, numbered pages to improve performance and readability.
- Inventory Context: The combination of product details (like name and SKU) with live stock data (like quantity on hand and unit cost) provided in a single search result.

2.4 Business Value

-

Efficiency: By providing all necessary data (stock levels and costs) during the initial search, the system saves the user from having to manually look up or type in information, significantly speeding up the creation of stock transfers.

- Accuracy: Because the system automatically pulls the current "average unit cost" and "quantity on hand" directly from the database, it reduces the risk of human error during data entry.
- Performance: The use of pagination ensures that the search remains fast and reliable, even as the company's product catalog grows over time.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/stock-transfers

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Stock Transfer feature allows users to create a formal record of moving inventory between two locations within the Lumi ERP system. This process ensures that inventory movements are tracked accurately, validated for errors, and recorded in a "draft" state for further processing. The system is designed to be robust, preventing duplicate entries and ensuring that all data—from the transfer header to individual product lines—is saved reliably as a single, complete unit.

1.2 Step-by-Step Flow

1. Duplicate Prevention: The system checks if a transfer with the same unique request ID has already been processed. If it has, the system returns the existing record instead of creating a duplicate.
2. Validation: The system verifies that the source and destination locations are different and that the list of items to be transferred is valid (e.g., quantities must be greater than zero).
3. Transaction Initiation: The system begins a secure process to save the transfer. If any part of this process fails, the entire operation is canceled to prevent incomplete or corrupted data.
4. Header Creation: A new transfer record is created in "draft" status. If a reference code is not provided, the system automatically generates one.
5. Snapshot and Calculation: For every product in the transfer, the system captures the current stock levels and average costs at that exact moment. It uses these "snapshots" to calculate the value of the transfer, ensuring the data is based on real-time system information rather than manual input.
6. Finalization: The system updates the transfer header with the total calculated value and saves the entire document.
7. Confirmation: Upon success, the system returns the details of the newly created transfer so the user can immediately view the document.

1.3 Key Concepts

- Idempotency: A safety mechanism that ensures submitting the same request multiple times does not result in multiple transfers; it simply returns the original result.
- Transactional Processing: A "all-or-nothing" approach to saving data. If one part of the transfer fails, the entire record is discarded to ensure the database remains clean and accurate.
- Snapshotting: The act of recording the exact state of inventory and costs at the moment the transfer is created, providing an audit trail of what the system "saw" when the request was made.
-

Draft State: The initial status of a new transfer, allowing for review or adjustments before the movement is finalized.

1.4 Business Value

- Data Integrity: By automatically calculating totals and snapshotting stock levels, the system eliminates manual calculation errors and ensures that financial and inventory records are always based on verified system data.
- Operational Reliability: The "all-or-nothing" saving process prevents partial records, ensuring that users never have to deal with incomplete or "broken" transfer documents.
- Efficiency: The system handles administrative tasks—such as generating reference codes and preventing duplicate submissions—automatically, allowing staff to focus on managing inventory rather than managing system errors.

2. Data

2.1 Overview

This feature provides a reliable way to create stock transfer documents within the Lumi ERP system. It allows users to move inventory between locations while ensuring that all data—such as current stock levels, costs, and transfer totals—is captured accurately and consistently at the moment the transfer is created.

2.2 Step-by-Step Flow

1. Duplicate Check: The system checks if the request has already been processed. If the same request is sent twice (e.g., due to a double-click), the system returns the original document instead of creating a duplicate.
2. Validation: The system verifies the request details. It ensures that the source and destination locations are different and that the list of items to be transferred is not empty.
3. Data Processing: The system begins a secure "all-or-nothing" operation to ensure data integrity.
4. Snapshotting: For every item in the transfer, the system automatically records the current stock levels at both the source and destination, as well as the current average cost of the product.
5. Calculation: The system calculates the total value of the transfer based on the recorded costs and quantities, rather than relying on values provided by the user.
6. Finalization: The transfer document is saved as a "draft," and the system returns the completed document details so the user can immediately view the record they just created.

2.3 Key Concepts

- Idempotency: A safety mechanism that prevents the same action from being performed multiple times, ensuring that resubmitting a form does not create duplicate records.
- Snapshotting: The process of capturing a "frozen" view of data (like current stock levels or costs) at the exact moment the transfer is created, providing an accurate audit trail.
- Transactional Write: A technical safeguard that ensures the entire document—including the header and all individual items—is saved as a single unit. If any part of the process fails, nothing is saved, preventing incomplete or corrupted data.
- Draft State: The initial status of a new transfer, allowing for review before the movement of goods is finalized.

2.4 Business Value

- Data Accuracy: By calculating totals and costs on the server side using real-time snapshots, the system eliminates errors caused by manual entry or outdated information.
- Reliability: The "all-or-nothing" saving process prevents partial data entries, ensuring that your inventory records remain clean and trustworthy.
- Efficiency: The system automatically handles reference codes and calculations, reducing the manual workload for users and speeding up the inventory management process.
- Error Prevention: Built-in validations prevent common mistakes, such as transferring items to the same location or submitting empty requests.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-orders/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to retrieve the specific details of a single stock order. By providing a unique order identifier, the system fetches the relevant header information—such as the order number, current status, and associated warehouse—to display on the Stock Order Details page. The system is designed to automatically ensure that users can only view orders belonging to their own company, maintaining strict data security.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided order identifier is formatted correctly. If the format is incorrect, the request is rejected.
2. Data Retrieval: The system searches the database for the requested order. It automatically filters this search to ensure the order belongs to the company of the person currently logged in.
3. Authorization Check: If the order cannot be found (either because it doesn't exist or because it belongs to a different company), the system reports that the order is not found.
4. Display: If the order is found and the user is authorized, the system returns the full details of the stock order.

1.3 Key Concepts

- Stock Order Header: The primary information for an order, including its status, creation date, and warehouse location, excluding the individual line items.
- Data Isolation: A security measure that ensures users can only access information relevant to their specific company, preventing unauthorized cross-company data viewing.
- Identifier Validation: A preliminary check to ensure the request is formatted correctly before the system attempts to process it, which helps prevent errors.

1.4 Business Value

This feature provides a reliable and secure way for staff to view the status and details of specific stock orders. By separating the order header from the individual line items, the system remains fast and responsive, allowing users to quickly verify order information without loading unnecessary data. Furthermore, the built-in security ensures that sensitive company inventory data remains protected and accessible only to authorized personnel.

2. Data

2.1 Overview

This feature allows users to retrieve detailed information for a specific stock order. When a user requests a stock order by its unique identifier, the system verifies the request, ensures the order belongs to the user's company, and returns the order details. This process is designed to be secure and efficient by focusing only on the "header" information of the order, keeping the data retrieval lightweight.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a specific stock order using its unique ID.
2. Format Validation: The system checks if the provided ID is in the correct format. If the format is invalid, the request is rejected.
3. Security & Ownership Check: The system attempts to find the order in the database. It automatically filters the search to ensure the order belongs to the company associated with the currently logged-in user.
4. Verification: If the order cannot be found (either because it doesn't exist or it belongs to a different company), the system returns a "not found" error.
5. Data Delivery: If the order is found and the user has permission to view it, the system returns the full details of that stock order.

2.3 Key Concepts

- Stock Order Header: The primary information about an order (such as status, warehouse location, and dates), excluding the individual line items.
- Multi-tenancy: A security practice where the system automatically restricts data access so that users can only view information belonging to their own company.
- Unique Identifier (ID): A specific code used to pinpoint one exact record in the database.
- Validation: The process of ensuring that incoming requests are formatted correctly before the system attempts to process them.

2.4 Business Value

This feature provides a reliable and secure way for staff to view the status and details of specific inventory movements. By enforcing company-level security at the database level, we ensure that sensitive inventory data is never accidentally exposed to unauthorized users. Additionally, by separating the "header" information from the "line items," the system remains fast and responsive, allowing for better performance when managing large orders.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-orders/:id/items

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to view the specific products (line items) associated with a single stock order. It allows users to retrieve a detailed list of items for a chosen order, with options to search by product name and navigate through large lists using pagination. The system automatically ensures that users can only access orders belonging to their own company.

1.2 Step-by-Step Flow

1. Verification: The system checks if the requested stock order exists and confirms that it belongs to the user's company. If the order is missing or belongs to another company, the request is denied.
2. Filtering: If a product name is provided, the system narrows down the list to only include items that match that name.
3. Retrieval: The system fetches the requested items in the order they were originally added to the stock order. It uses pagination to return a manageable number of items at a time.
4. Response: The system returns the total quantity of all items in the original order, along with the specific list of items requested. Each item in the list is assigned a row number, which resets based on the current page of results.

1.3 Key Concepts

- Pagination: A method of breaking a large list of items into smaller, manageable pages (e.g., 20 items per page) to improve performance and readability.
- Filtering: The ability to search for specific items within an order by typing a product name.
- Data Ownership: A security measure that ensures users can only view stock orders associated with their specific company.
- Total Order Quantity: A summary figure that represents the sum of all items in the order, which remains constant even if you filter the list to view only specific items.

1.4 Business Value

This feature improves inventory management efficiency by allowing staff to quickly locate specific products within a stock order without having to scroll through long lists. By providing a clear, paginated view and maintaining accurate total quantity reporting, it ensures that warehouse and procurement teams have reliable, easy-to-access information to verify shipments and manage stock levels effectively.

2. Data

2.1 Overview

This feature provides a way to retrieve a list of individual products (line items) associated with a specific stock order. It is designed to be secure, efficient, and easy to navigate, allowing users to view order details even when those orders contain a large number of items.

2.2 Step-by-Step Flow

1. Security Check: The system first verifies that the requested stock order exists and confirms it belongs to the company currently logged into the system. If the order cannot be found or belongs to a different company, the request is denied.
2. Data Retrieval: The system fetches the specific items for that order. It applies any search filters requested by the user and organizes the results in the order they were originally added to the system.
3. Pagination Calculation: The system counts the total number of items matching the search criteria to help the user navigate through pages of results.
4. Response Delivery: The system returns the requested list of items, the total quantity of the entire order (regardless of filters), and the pagination details (such as the current page and total count) to the user.

2.3 Key Concepts

- Data Isolation: A security measure that ensures users can only access stock orders that belong to their own company.
- Pagination: A method of breaking a large list of items into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down the list of items (e.g., searching for a specific product name) without affecting the overall order totals.
- Insertion Order: The default way items are displayed, showing them in the sequence they were originally added to the order.

2.4 Business Value

This feature enables staff to efficiently manage and audit inventory by providing a clear, searchable view of what is contained within a specific stock order. By including pagination and robust security checks, the system remains fast and reliable even as order sizes grow, while ensuring that sensitive company data remains protected and accessible only to authorized users.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/stock-orders/:id/confirm

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to finalize a stock order within the Lumi ERP system. By triggering this action, a stock order is moved from a "draft" state to a "confirmed" state. This process ensures that the order is officially recognized in the system, while maintaining a clear audit trail of the change.

1.2 Step-by-Step Flow

1. Identification: The system receives a request to confirm a specific stock order using its unique ID.
2. Verification: The system checks that the order exists and belongs to your company. If the order cannot be found, the request is rejected.
3. Status Check: The system verifies that the order is currently in "draft" status. If the order has already been confirmed or is in another state, the request is rejected to prevent accidental changes.
4. Finalization: Once validated, the system updates the order status to "confirmed" and records the exact time of confirmation.
5. Audit Logging: Simultaneously, the system creates a history record to document the transition from "draft" to "confirmed," including who performed the action.
6. Confirmation: The system returns the updated order details to confirm the process was successful.

1.3 Key Concepts

- Stock Order: A document or record representing a request for inventory movement.
- Draft State: The initial phase of an order where it can still be edited before being officially finalized.
- Confirmed State: The final phase of an order, indicating it has been reviewed and approved.
- Workflow History: An audit log that tracks the lifecycle of an order, showing when it changed status and who authorized the change.
- Transaction: A safety mechanism that ensures the status update and the history log are both saved successfully; if one fails, the entire process is rolled back to prevent data errors.

1.4 Business Value

- Data Integrity: By restricting confirmation to "draft" orders only, the system prevents duplicate processing or accidental modifications to orders that are already finalized.
- Accountability: The automatic creation of a history record ensures there is a clear, unchangeable trail of who confirmed an order and when, which is essential for internal reporting and auditing.
-

Operational Efficiency: This feature provides a standardized, reliable way for team members to transition orders through the supply chain workflow without manual intervention or risk of inconsistent data.

2. Data

2.1 Overview

The "Confirm Stock Order" feature allows authorized users to finalize a stock order that is currently in a "draft" state. This action officially transitions the order to a "confirmed" status, records the exact time of confirmation, and logs who performed the action. This process ensures that stock orders are tracked accurately within the system's workflow history.

2.2 Step-by-Step Flow

1. Locate the Order: The system identifies the specific stock order using the provided ID and verifies that it belongs to the user's company.
2. Validate Status: The system checks if the order is currently in "draft" mode. If the order has already been confirmed or is in another state, the request is rejected to prevent duplicate or invalid processing.
3. Update Order Details: The system updates the order status to "confirmed," records the current date and time, and saves the ID of the user who performed the update.
4. Log History: Simultaneously, the system creates a permanent record in the workflow history, noting the transition from "draft" to "confirmed" and identifying the user responsible for the change.
5. Finalize: Once these steps are successfully completed, the system confirms the update is finished.

2.3 Key Concepts

- Draft State: The initial status of a stock order, indicating it is still being prepared and has not yet been finalized.
- Atomic Transaction: A safety mechanism that ensures the order update and the history log are processed together; if one part fails, the entire action is canceled to prevent data inconsistencies.
- Workflow History: A permanent audit trail that tracks the lifecycle of a stock order, specifically recording status changes and the individuals who initiated them.
- Conflict Check: A validation step that prevents users from confirming an order that is no longer in the correct state (e.g., trying to confirm an order that is already confirmed).

2.4 Business Value

- Data Integrity: By requiring orders to be in a "draft" state before confirmation, the system prevents accidental or duplicate processing of stock orders.
-

Accountability: The automated logging of the user who confirmed the order provides a clear audit trail, which is essential for internal oversight and troubleshooting.

- Operational Clarity: Moving orders from "draft" to "confirmed" provides real-time visibility into which orders are ready for the next stage of the supply chain process.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/stock-orders/:id/cancel

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to cancel an existing stock order within the Lumi ERP system. By using this endpoint, users can transition an order that is no longer needed into a "cancelled" state. This action is final, ensuring that the order's history is accurately tracked while maintaining the integrity of the inventory records.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to cancel a specific stock order identified by its unique ID.
2. Validation: The system verifies that the order exists and belongs to the user's company.
3. Status Check: The system confirms the order is currently in a "draft" or "confirmed" state. If the order is already in another state (such as already cancelled or completed), the request is rejected.
4. Processing: If valid, the system updates the order status to "cancelled" and records the user who performed the action.
5. History Logging: Simultaneously, the system creates a permanent record in the order's history log to document the cancellation.
6. Confirmation: The system returns a success response containing the updated order details, including the new status and the time of the update.

1.3 Key Concepts

- Stock Order: A formal request for inventory movement within the ERP system.
- Workflow State: The current phase of an order (e.g., draft, confirmed, or cancelled).
- Terminal State: A status that cannot be changed further; once an order is "cancelled," it cannot be reopened.
- Transaction: A safety mechanism that ensures both the order update and the history log entry are saved together; if one fails, the entire process is rolled back to prevent data inconsistencies.
- Ownership Validation: A security check that ensures users can only modify orders belonging to their own company.

1.4 Business Value

- Operational Accuracy: Prevents accidental or unauthorized modifications to orders that have already progressed beyond the cancellation window.
- Audit Readiness: By automatically logging the cancellation in the history table, the system provides a clear trail of who cancelled an order and when, which is essential for inventory reporting and accountability.
-

Process Discipline: Enforces a strict workflow where cancelled orders are treated as final, encouraging users to create new, accurate orders rather than attempting to modify invalid ones.

2. Data

2.1 Overview

This feature provides a way to cancel an existing stock order within the Lumi ERP system. When a user triggers this action, the system updates the order's status to "cancelled" and creates a permanent record of this change in the system's history. This process is designed to be safe and reliable, ensuring that only valid orders can be cancelled and that every cancellation is tracked for auditing purposes.

2.2 Step-by-Step Flow

1. Locate and Secure: The system identifies the specific stock order requested and locks it to ensure no other changes can happen while the cancellation is being processed.
2. Verify Existence: The system checks if the order actually exists and confirms that it belongs to the company making the request.
3. Validate Status: The system checks the current state of the order. Only orders that are currently in "draft" or "confirmed" status are eligible for cancellation.
4. Update Status: If valid, the system updates the order status to "cancelled," records who performed the action, and updates the timestamp.
5. Log History: Simultaneously, the system adds an entry to the order's history log to maintain a clear audit trail of the status change.
6. Finalize: The transaction is completed, and the updated order details are returned to the user.

2.3 Key Concepts

- Atomic Transaction: A "all-or-nothing" process where the status update and the history log entry must both succeed together; if one fails, the entire action is cancelled to prevent data errors.
- Terminal State: Once an order is marked as "cancelled," it cannot be changed again. If a user still needs the items, they must create a brand-new stock order.
- Workflow History: A dedicated record that tracks the lifecycle of an order, providing transparency on when and by whom changes were made.
- Validation: Built-in safeguards that prevent the system from processing invalid requests, such as trying to cancel an order that doesn't exist or one that has already been processed.

2.4 Business Value

This feature improves inventory management by providing a clean, controlled way to handle cancelled orders. By enforcing strict rules on which orders can be cancelled, the system prevents accidental data loss and ensures that inventory records remain accurate. Furthermore, the automatic logging of these cancellations provides a reliable audit trail, which is essential for operational transparency and accountability.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/stock-orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to create a new stock order and its associated items in one single action. By sending a request to this endpoint, you can define the warehouse source, the destination store, and a list of specific products to be ordered. The system automatically handles the calculations for order costs and ensures that all information is saved accurately and consistently.

1.2 Step-by-Step Flow

1. Initiation: The system receives a request containing the order details (such as the reference code, warehouse locations, and the list of items).
2. Validation: The system checks if the provided reference code is unique. If a code already exists, the request is rejected to prevent duplicate entries.
3. Preparation: The system creates a new order record, automatically filling in administrative details like the creator's ID, the current date, and the company association.
4. Item Processing: For every product in the order, the system calculates the total cost based on the quantity and the average cost of the item. It then saves each item as part of the order.
5. Finalization: Once all items are processed, the system calculates the total order amount for the entire request and saves the final order record.
6. Confirmation: If everything is successful, the system confirms the creation of the order. If any part of the process fails, the entire operation is canceled to ensure no partial or incorrect data is saved.

1.3 Key Concepts

- Stock Order: A formal request to move inventory from a warehouse to a specific store.
- Reference Code: A unique identifier (like an order number) used to track and distinguish specific stock orders.
- Transaction: A "safety-first" approach where the system treats the entire order and its list of items as one single unit of work; if one part fails, the whole thing is undone to keep records clean.
- Workflow State: The current status of the order (e.g., pending, approved, or in-transit).
- Calculated Fields: Values like "order amount" that the system computes automatically based on the items provided, reducing the need for manual entry and preventing calculation errors.

1.4 Business Value

- Data Integrity: By using a single transaction, the system guarantees that you will never have an "orphaned" order (an order without items) or incomplete data, ensuring your inventory reports remain accurate.
-

Efficiency: This feature automates the calculation of order costs and the assignment of system-managed fields (like timestamps and user IDs), saving time and reducing manual data entry errors.

- Reliability: The built-in validation for unique reference codes prevents confusion and conflicts in your supply chain tracking, ensuring that every order is uniquely identifiable.

2. Data

2.1 Overview

The `POST /api/stock-orders` feature allows users to create a new stock order and its associated line items in one single action. This ensures that when you request a transfer of goods between locations, the system captures both the high-level order details (such as the source warehouse, destination store, and due date) and the specific list of products being ordered simultaneously.

2.2 Step-by-Step Flow

1. Validation: The system checks if the provided reference code is unique to prevent duplicate orders.
2. Initialization: The system prepares the order by generating a unique ID and capturing the current date and time.
3. Order Creation: The main stock order record is created, automatically tagging it with the current user's information and the company ID.
4. Item Processing: The system iterates through the list of products provided in the request, creating individual line items for each and linking them to the main stock order.
5. Finalization: The entire process is treated as a single "transaction." If any part of the process fails (e.g., an invalid product entry), the system cancels the entire operation to ensure no partial or incorrect data is saved.

2.3 Key Concepts

- Transaction: A safety mechanism that ensures all parts of an order are saved together. If one part fails, the entire request is rolled back to keep the data clean and consistent.
- Reference Code: A unique identifier for the order that helps prevent accidental duplication of records.
- System-Managed Fields: Information that the software handles automatically—such as timestamps, user IDs, and unique record IDs—so the user doesn't have to provide them manually.
- Stock Order Items: The individual product lines within an order, which track specific quantities and remarks for each item being moved.

2.4 Business Value

This feature streamlines inventory management by allowing for "all-or-nothing" order creation. By bundling the order and its items into a single request, the business reduces the risk of data errors or mismatched records. This ensures that inventory tracking remains accurate and reliable, providing a clear audit trail of who created the order and when, while maintaining strict consistency across the entire supply chain.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/purchase_returns/new

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Create Purchase Return" feature allows the system to officially record items being returned by the company. This process ensures that both the main return document (the header) and the specific list of items being returned are saved together as a single, reliable transaction. The system automatically generates tracking information, such as unique reference codes and timestamps, to keep inventory records accurate and organized.

1.2 Step-by-Step Flow

1. Validation: The system checks that the incoming request is formatted correctly.
2. Duplicate Check: The system looks for a unique request identifier to ensure the same return isn't processed twice by mistake. If it has already been processed, it simply returns the existing record.
3. Transaction Start: The system begins a secure "all-or-nothing" process to ensure data integrity.
4. Header Creation: A new return document is created, and the system automatically assigns it a unique ID, a reference code, and the current date/time.
5. Item Processing: The system reviews each item in the request. It verifies that every product exists in the inventory database before adding it to the return.
6. Finalization: If all items are valid, the system saves the entire return (header and items) permanently. If any part of the process fails, the system cancels the entire operation to prevent incomplete or incorrect data from being saved.

1.3 Key Concepts

- Transaction: A safety mechanism that ensures either the entire return is saved successfully or nothing is saved at all, preventing partial or corrupted data.
- Idempotency Token: A unique identifier used to prevent the same request from being submitted multiple times, which protects against accidental duplicate entries.
- Header: The main record for the purchase return that contains high-level information, such as the type of return and the date it was created.
- Validation: The process of checking that all provided information (like product IDs) is accurate and exists within the system before finalizing the record.

1.4 Business Value

This feature provides a reliable and automated way to manage inventory returns. By using a transaction-based approach, the business avoids "ghost" records or mismatched inventory data. The inclusion of duplicate protection

and automated reference generation reduces manual administrative work and minimizes the risk of human error, ensuring that the company's inventory levels remain accurate and auditable.

2. Data

2.1 Overview

This feature allows the system to record a new "Company Purchase Return." It captures the high-level details of the return (the header) and the specific list of items being returned. The system is designed to be robust, ensuring that either the entire return is saved successfully or nothing is saved at all, preventing incomplete or corrupted data.

2.2 Step-by-Step Flow

1. Duplicate Check: The system first checks if a return with the same unique request identifier has already been processed. If it has, the system returns the existing record instead of creating a new one.
2. Transaction Start: The system begins a secure database operation to ensure all data is saved together.
3. Header Creation: The system creates the main return record, automatically generating a unique reference code and timestamps for the entry.
4. Item Processing: The system adds each individual item from the request to the return, linking them to the main header record created in the previous step.
5. Finalization: If all steps succeed, the transaction is finalized, and the system confirms the creation. If any part of the process fails, the system cancels the entire operation to ensure no partial data is saved.
6. Response: The system returns the newly created record details or provides an appropriate error message if the request was invalid or an unexpected issue occurred.

2.3 Key Concepts

- Idempotency: A safety mechanism that uses a unique request identifier to ensure that if the same request is sent multiple times (e.g., due to a network retry), the system does not create duplicate records.
- Transaction: A "all-or-nothing" approach to saving data. It ensures that the return header and its associated items are treated as a single unit of work.
- Header: The primary record that classifies the return and holds general information, such as the return type and creation date.
- Items: The specific products and quantities associated with a return, which are linked back to the main header record.

2.4 Business Value

This feature provides a reliable and consistent way to track inventory returns within the Lumi ERP. By using an idempotency check, it prevents accidental duplicate entries, which protects inventory accuracy. Furthermore, the "all-or-nothing" transaction logic ensures that the system never ends up with "orphaned" items or incomplete return records, maintaining high data integrity for financial and inventory reporting.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/inventory/purchase-returns/standard/:id/approval

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides the necessary data to populate the "Approve/Confirm" screen for a standard purchase return. When a user navigates to the approval page for a specific return, this system retrieves all relevant details—such as the items being returned, supplier information, and warehouse details—to ensure the user has the correct context to finalize the return process.

1.2 Step-by-Step Flow

1. Locate the Record: The system searches for the specific purchase return record requested by the user, ensuring it belongs to the correct company.
2. Verify Existence: If the record cannot be found, the system notifies the user that the request is invalid.
3. Check Workflow Status: The system confirms that the return is currently in the "Sent to Supplier" state. If the return is in any other state, the system prevents access to the approval form to maintain process integrity.
4. Gather Details: Once validated, the system collects the associated warehouse, supplier, and itemized return data.
5. Display Information: The system compiles this information, including the quantities returned and the supplier-confirmed totals, and presents it to the user for review.

1.3 Key Concepts

- Workflow State: A status indicator that tracks where a document is in its lifecycle; in this case, the return must be "Sent to Supplier" before it can be approved.
- Purchase Return: A formal record of items being sent back to a supplier, including details on what was sent and what the supplier has acknowledged receiving.
- Approval Form: The user interface where staff verify that the items received by the supplier match the items originally sent, allowing them to finalize the return.

1.4 Business Value

This feature ensures data accuracy and process compliance by preventing users from approving returns that are not ready for finalization. By centralizing all relevant return information—such as supplier confirmation and warehouse details—into a single view, it streamlines the reconciliation process, reduces manual errors, and provides a clear audit trail for inventory adjustments.

2. Data

2.1 Overview

This feature provides a way for users to retrieve the specific details of a "Purchase Return" record so they can review and approve it. It acts as the data source for the approval screen, ensuring that all necessary information—such as the items being returned, the warehouse involved, and the supplier's confirmed quantities—is available for the user to verify before finalizing the process.

2.2 Step-by-Step Flow

1. Request: The system receives a request to view a specific purchase return record for approval.
2. Verification: The system checks if the record exists and belongs to the current company. If it cannot be found, the request is rejected.
3. Status Check: The system verifies the current status of the return. It will only proceed if the status is set to "Sent to Supplier." If the status is anything else, the request is rejected to prevent premature or invalid approvals.
4. Data Gathering: If the checks pass, the system collects all relevant details, including the warehouse, supplier, individual return items, and any notes attached to the record.
5. Calculation: The system calculates the total quantity confirmed by the supplier based on the individual items.
6. Response: The system presents a complete summary of the return, ready to be displayed on the approval form.

2.3 Key Concepts

- Purchase Return: A formal record of goods being sent back to a supplier.
- Workflow State: A status indicator that tracks where the return is in the approval process; this feature specifically requires the "Sent to Supplier" state.
- Aggregate Data: A collection of related information (like supplier details, warehouse location, and item lists) bundled together into a single view for the user.
- Company Scope: A security measure that ensures users can only access records that belong to their specific organization.

2.4 Business Value

This feature ensures data integrity and process control. By requiring the record to be in a "Sent to Supplier" state before it can be opened for approval, the system prevents users from accidentally modifying or approving returns that are not yet ready. It provides a clean, consolidated view of the return, which reduces manual effort and minimizes errors during the final confirmation stage of the inventory return process.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/inventory/purchase-returns/standard/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve the full details of a specific "Standard Purchase Return" record. When a user views a return record in the inventory module, this functionality gathers all the necessary information—such as the supplier, warehouse, associated purchase documents, and the specific items being returned—to display on the screen.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a specific purchase return record using its unique ID.
2. Verification: The system checks if the requested record exists and confirms that it belongs to the user's current company.
3. Error Handling: If the record cannot be found or does not belong to the company, the system returns an error message indicating the record is unavailable.
4. Data Retrieval: If the record is found, the system gathers the primary return details (such as the status and dates) along with the list of individual items included in that return.
5. Response: The system compiles all this information into a single package and sends it back to the user's interface for display.

1.3 Key Concepts

- Purchase Return: A formal record documenting items sent back to a supplier, typically linked to original purchase orders, deliveries, or invoices.
- Company Scope: A security measure that ensures users can only access records that belong to their specific organization.
- Workflow State: The current status of the return (e.g., Draft, Pending, or Completed), which dictates what actions a user can take next.
- Associated Items: The specific products or goods that are being returned, which are tracked individually within the main return record.

1.4 Business Value

This feature is essential for inventory transparency and financial accuracy. By allowing users to quickly pull up the details of a purchase return, the system ensures that staff can verify return history, track the status of goods moving back to suppliers, and maintain a clear audit trail. This visibility helps prevent errors in inventory counts and ensures that financial records—such as invoices and payments—remain synchronized with physical stock movements.

2. Data

2.1 Overview

This feature provides a comprehensive view of a "Standard Purchase Return" record within the Lumi ERP system. When a user navigates to the details page for a specific return, this functionality gathers all relevant information—such as the items returned, associated financial data, and links to original purchase documents—to display a complete summary of the transaction. It also identifies the current status of the return to ensure the user sees the correct action buttons (e.g., "Approve" or "Cancel") based on where the return is in its lifecycle.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a specific purchase return record using its unique identifier.
2. Data Retrieval: The system searches the database for the record, ensuring it belongs to the user's company.
3. Information Aggregation: If found, the system collects all related details, including:

* The return header and audit timestamps.

* Links to the original Purchase Order, Delivery, and Invoice.

* Warehouse and Supplier details.

* Financial summaries and accounting journal references.

* The list of items being returned.

4. Workflow Evaluation: The system checks the current "workflow state" of the return to determine which actions are currently available to the user.
5. Response Delivery: The system compiles all this information into a structured format and sends it to the user's screen. If the record cannot be found, the system returns an error message.

2.3 Key Concepts

– Purchase Return Standard: A formal record documenting the return of goods to a supplier, linked to previous purchasing documents.

– Workflow State: The current stage of the return process (e.g., Draft, Pending, Completed), which dictates what the user is allowed to do next.

– Aggregate Data: A collection of related information pulled from multiple sources (like suppliers, warehouses, and financial records) to provide a "single pane of glass" view of the transaction.

–

Audit Fields: Tracking information that records when a document was created or last modified, ensuring transparency and accountability.

2.4 Business Value

This feature ensures that warehouse and procurement staff have immediate access to the full context of a return without needing to manually search through multiple different screens. By automatically linking the return to its original purchase order, delivery, and invoice, the system reduces administrative errors and speeds up the reconciliation process. Furthermore, by dynamically showing only the relevant action buttons based on the workflow state, the system guides users through the correct business process, preventing unauthorized or out-of-sequence actions.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/inventory/purchase-returns/standard/:id/send-to-supplier

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to officially transition a "Purchase Return" document from a preliminary "Draft" status to a "Sent to Supplier" status. This action is typically triggered when a user confirms they are ready to share the return details with their supplier. The system ensures that only documents currently in the "Draft" stage can be moved forward, maintaining the integrity of the inventory workflow.

1.2 Step-by-Step Flow

1. Locate the Record: The system searches for the specific purchase return document requested by the user within the current company's records.
2. Verify Status: The system checks if the document is currently in "Draft" status. If the document has already been processed or is in a different state, the request is blocked to prevent errors.
3. Update Status: Once verified, the system updates the document status to "Sent to Supplier." It also automatically records the exact time the action occurred and identifies which user performed the update.
4. Confirm Success: The system returns a confirmation to the user, allowing the application to refresh the screen and display the updated status.

1.3 Key Concepts

- Purchase Return: A document used to track items being sent back to a supplier, typically for refunds or replacements.
- Draft State: The initial phase of a document where it can still be edited before being finalized and sent externally.
- Workflow State: The current stage of a document in its lifecycle (e.g., Draft vs. Sent to Supplier).
- Authentication Scope: A security measure ensuring that users can only view or modify documents that belong to their specific company.

1.4 Business Value

- Process Control: By restricting the "Sent to Supplier" action to "Draft" documents only, the system prevents accidental duplicate submissions or the modification of records that have already been finalized.
- Audit Readiness: Automatically capturing the date, time, and the user responsible for the action provides a clear trail of accountability for inventory returns.
- Operational Efficiency: Automating the status transition reduces manual data entry and ensures that the inventory system accurately reflects the real-time status of returns being handled by suppliers.

2. Data

2.1 Overview

This feature allows users to finalize a purchase return document by transitioning it from a "Draft" state to a "Sent to Supplier" state. This action is triggered when a user confirms the process within the application, ensuring that the system accurately tracks when a return request has been officially communicated to a supplier.

2.2 Step-by-Step Flow

1. Request Initiation: The user triggers the "Send to Supplier" action from the purchase return details page.
2. Verification: The system locates the specific purchase return record and confirms it belongs to the user's company.
3. State Validation: The system checks if the document is currently in "Draft" status. If the document has already been sent or is in another state, the action is blocked to prevent errors.
4. Update Execution: If the validation passes, the system updates the document status to "Sent to Supplier."
5. Audit Logging: The system automatically records the exact date and time the action occurred and identifies which user performed the update.
6. Confirmation: Upon success, the system notifies the user and refreshes the page to display the updated status.

2.3 Key Concepts

- Purchase Return (Standard): A formal document used to track items being returned to a supplier.
- Workflow State: The current phase of the document (e.g., "Draft" vs. "Sent to Supplier"), which dictates what actions can be performed on it.
- Audit Trail: The automatic recording of "who" updated a record and "when," ensuring accountability and accurate record-keeping.
- Validation: A safety check that ensures a document is in the correct state before allowing a change, preventing accidental or duplicate processing.

2.4 Business Value

This feature enforces a structured workflow for inventory management. By requiring a document to be in "Draft" before it can be "Sent to Supplier," the system prevents premature processing and ensures that all returns are properly reviewed before being finalized. Additionally, the automatic timestamping and user tracking provide a reliable history for auditing and supplier communication, reducing the risk of errors in the supply chain process.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/inventory/purchase-returns/standard/:id/approve

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to finalize a "Purchase Return" process by confirming the quantities received or agreed upon by the supplier. When a user approves a return, the system updates the individual item quantities, records any final notes, and transitions the return document to an "Approved" status. This ensures that the inventory records accurately reflect the supplier's confirmation before the return is officially closed.

1.2 Step-by-Step Flow

1. Verification: The system checks that the specific purchase return exists and is currently in the "Sent to Supplier" stage. If the return is in any other stage or cannot be found, the process stops to prevent errors.
2. Item Update: The system reviews the list of items provided in the request. It verifies that each item belongs to the correct return and that the supplier-confirmed quantities are valid (e.g., no negative numbers).
3. Data Recording: Once the items are validated, the system saves the supplier-confirmed quantities for each item.
4. Finalization: The system updates the main return document with any provided notes, changes the status to "Approved / Confirmed by Supplier," and logs the exact time and user responsible for the approval.
5. Confirmation: Upon success, the system returns the updated record details, allowing the user interface to display a success message and refresh the page.

1.3 Key Concepts

- Purchase Return: A formal document tracking items being sent back to a supplier.
- Workflow State: The current phase of the return process; in this case, it must be "Sent to Supplier" before it can be approved.
- Supplier Confirmed Quantity: The actual amount of items the supplier has agreed to accept for return, which may differ from the original request.
- Approval Metadata: The system-generated record of who approved the return and exactly when it happened, ensuring accountability.

1.4 Business Value

- Data Accuracy: By requiring supplier-confirmed quantities, the system ensures that inventory and financial records match the actual agreement with the supplier.
- Process Control: The workflow state validation prevents users from accidentally approving returns that are not ready or have already been processed.
-

Audit Readiness: Automatically recording the approval time and the user responsible provides a clear trail of accountability for all inventory returns.

2. Data

2.1 Overview

This feature enables users to finalize a "Purchase Return" record once a supplier has confirmed the return details. When a user approves a return, the system updates the status of the document, records the quantities confirmed by the supplier, and logs the approval details (such as who approved it and when). This ensures that the inventory records accurately reflect the outcome of the return process.

2.2 Step-by-Step Flow

1. Request Initiation: The user triggers the approval process from the Purchase Return screen.
2. Verification: The system checks that the record exists and is currently in the "Sent to Supplier" state. If the record is missing or in a different state, the process stops to prevent errors.
3. Data Validation: The system verifies that the quantities provided for each item are valid.
4. Record Update: If all checks pass, the system performs the following updates:

* Changes the document status to "Approved / Confirmed by Supplier."

* Saves the supplier-confirmed quantities for each item.

* Records the approval timestamp, the user who performed the action, and any optional notes provided.

5. Confirmation: Upon success, the system confirms the update, allowing the user to see the finalized status on the detail page.

2.3 Key Concepts

- Workflow State: The current stage of the return process (e.g., "Sent to Supplier" vs. "Approved"). This acts as a guardrail to ensure documents are only approved at the correct time.
- Supplier Confirmed Quantity: The actual amount of goods agreed upon by the supplier, which may differ from the original return request.
- Audit Trail: The automatic recording of "who" (user) and "when" (timestamp) an action was taken, ensuring accountability for inventory changes.
- Transaction: A safety mechanism that ensures all updates (status change, item quantities, and audit logs) happen together; if any part fails, none of the changes are saved.

2.4 Business Value

This feature streamlines the inventory reconciliation process by providing a clear, digital hand-off between the company and the supplier. By capturing the supplier's confirmed quantities directly in the system, the business reduces manual data entry errors, maintains an accurate audit trail for financial and inventory reporting, and ensures that purchase returns are only finalized once all parties have agreed on the terms.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/purchase-orders?{filters}&{pagination}&{sorting}

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of purchase orders. It is designed to be flexible, allowing users to search for specific orders, organize them in a particular order, and view them in manageable chunks (pagination). The system automatically ensures that users only see purchase orders belonging to their own company based on their login session.

1.2 Step-by-Step Flow

1. Identify User: The system identifies the user's company based on their active login session to ensure data privacy.
2. Receive Request: The system receives the search criteria, which may include filters (like order type or date range), sorting preferences, and pagination settings (how many items to show and where to start).
3. Validate Inputs: The system checks the request for errors. For example, it ensures that a "start date" is not set after an "end date." If the inputs are invalid, it returns an error message.
4. Apply Filters and Sorting: The system searches the database for purchase orders that match the provided filters, applies the requested sorting, and limits the results to the requested page size.
5. Return Results: The system returns the list of matching purchase orders. If no orders match the criteria, it returns an empty list rather than an error.

1.3 Key Concepts

- Filters: Specific criteria used to narrow down the list of purchase orders, such as the type of order, whether it is a fixed asset, its current workflow status, or a specific date range.
- Pagination: A method to break a large list of results into smaller, manageable pages by defining a "limit" (how many items per page) and an "offset" (how many items to skip).
- Sorting: The ability to arrange the results by a specific field (like the creation date) in either ascending or descending order.
- Session-Based Scoping: A security measure that automatically restricts the search to the current company, preventing users from accidentally accessing data from other organizations.

1.4 Business Value

This feature empowers users to efficiently manage their procurement workflow by quickly finding the exact purchase orders they need. By supporting filtering and sorting, it reduces the time spent manually searching through records. Furthermore, the built-in pagination ensures that the system remains fast and responsive, even as the volume of purchase orders grows over time.

2. Data

2.1 Overview

This feature provides a secure and efficient way for users to retrieve a list of purchase orders associated with their company. It allows users to search through their records using specific criteria, organize the results in a preferred order, and view them in manageable chunks (pagination). The system automatically ensures that users only see data belonging to their own company and validates all search requests to prevent errors.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies the user's session to ensure they are authorized and identifies which company the request belongs to.
2. Request Validation: The system checks the search criteria. If a date range is provided, it confirms that the "start date" is not after the "end date." If the request is invalid, the system provides a clear error message.
3. Data Filtering: The system narrows down the list of purchase orders based on the user's input, such as order type, asset status, workflow stage, or a specific date range.
4. Sorting: The system organizes the filtered results. By default, it shows the most recently created orders first, though users can choose to sort by other criteria.
5. Pagination: To keep the data easy to read, the system returns a specific number of results at a time (defaulting to 20).
6. Result Delivery: The system returns the final list of matching purchase orders. If no orders match the criteria, it returns an empty list rather than an error.

2.3 Key Concepts

- Filtering: The ability to narrow down a large list of records to only those that meet specific requirements (e.g., "show me only fixed asset orders").
- Pagination: A method of breaking a large set of data into smaller, manageable pages to improve performance and readability.
- Sorting: The process of arranging records in a specific order, such as by date or amount, to help users find information faster.
- Company Scoping: A security measure that automatically restricts data access so that a user can only view records belonging to their specific organization.

2.4 Business Value

This feature improves operational efficiency by allowing staff to quickly locate specific purchase orders without manually scanning through entire databases. By providing robust filtering and sorting, the system supports better decision-making and faster auditing. Furthermore, the built-in validation and security checks ensure that the data remains accurate and protected, preventing unauthorized access and reducing the likelihood of user errors during the search process.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/stock-outgoings

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a secure way for the system to record a "Stock Outgoing" document. When a user needs to remove items from inventory, this process ensures that the request is valid, authorized, and backed by sufficient stock levels before creating a draft record. The system automatically handles document numbering and pricing to ensure data consistency and prevent manual entry errors.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to manage inventory at the specified location.
2. Input Validation: The system checks that the request includes at least one product line and that all requested quantities are greater than zero.
3. Stock Verification: For every product requested, the system checks the current inventory at that location. If the requested quantity exceeds what is currently available, the entire request is rejected to prevent inventory discrepancies.
4. Pricing: The system automatically calculates the current average cost for each product. This ensures the outgoing document reflects accurate financial data without relying on user input.
5. Document Creation: Once all checks pass, the system generates a unique document number and saves the request as a "Draft" in the database.

1.3 Key Concepts

- Stock Outgoing: A formal record used to track items leaving a specific inventory location.
- Draft Status: The initial state of a document, allowing for review before the stock is officially deducted from the system.
- Server-Side Validation: Security and logic checks performed by the system rather than the user's device, ensuring that data cannot be manipulated or bypassed.
- Inventory Integrity: The practice of verifying stock levels in real-time to ensure that outgoing requests never exceed available supply.

1.4 Business Value

- Accuracy: By automating document numbering and cost calculations, the system eliminates human error and ensures financial reporting is consistent.
- Control: The strict validation of stock levels prevents "negative inventory" scenarios, ensuring that the system always reflects the physical reality of the warehouse.
-

Security: Role-based access checks ensure that only authorized personnel can initiate stock movements at specific locations, reducing the risk of unauthorized inventory loss.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/service-work-orders?{filters}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a search tool for the "Work Order Picker" used within the New Stock Outgoing form. It allows users to quickly find specific service work orders by typing a reference code. To ensure data security and performance, the search is restricted to the specific store location selected by the user and requires a minimum of three characters to initiate a search.

1.2 Step-by-Step Flow

1. Validation: The system checks that both the store location and a search term (at least three characters long) have been provided. If these are missing or too short, the request is rejected.
2. Authorization: The system verifies that the user has the necessary permissions to access work orders for the specific store requested.
3. Query Execution: The system searches the database for work orders that match the provided reference code within the user's company and the selected store. It retrieves a limited list of results (defaulting to 20 items).
4. Response: The system returns the matching work orders, including their unique ID, reference code, and current status, allowing the picker to display the information to the user.

1.3 Key Concepts

- Reference Code: The unique identifier or document number used to track a specific service work order.
- Store Scoping: A security and organizational measure that ensures users only see work orders associated with the specific store they are currently working in.
- Pagination: A method of breaking large lists of data into smaller, manageable chunks (using "limit" and "offset") to keep the application fast and responsive.
- Status (aasm_state): The current lifecycle stage of a work order (e.g., pending, completed, or cancelled). This information is provided so the system can eventually determine if a work order is eligible to be picked.

1.4 Business Value

This feature streamlines the inventory process by enabling staff to accurately and quickly locate the correct service work order when preparing outgoing stock. By enforcing store-level access and requiring specific search criteria, it reduces manual errors, prevents unauthorized access to data, and ensures that the picker interface remains performant and easy to navigate.

2. Data

2.1 Overview

This feature provides a search tool for the "Service Work Order" picker used within the New Stock Outgoing form. It allows users to quickly find specific work orders by typing a reference code. To ensure data security and performance, the search is restricted to the user's company and a specific store location, and it only triggers once a meaningful search term (at least three characters) is provided.

2.2 Step-by-Step Flow

1. Authentication: The system verifies the user's identity. If the user is not logged in, the request is rejected.
2. Parameter Validation: The system checks that a store ID is provided and that the search term (reference code) contains at least three characters. If these requirements aren't met, the request is rejected.
3. Authorization: The system confirms the user has permission to access the specific store requested. If not, the request is denied.
4. Data Retrieval: The system searches the database for work orders that match the provided reference code within the specified store and company.
5. Response: The system returns a list of matching work orders, including their unique ID, reference code, and current status, allowing the user to select the correct job.

2.3 Key Concepts

- Reference Code: The unique identifier or document number used to track a specific service work order.
- Store Scoping: A security and organizational measure that ensures users only see work orders associated with the specific location they are currently working in.
- Status (AASM State): The current lifecycle stage of a work order (e.g., "completed"). This is included in the search results so the system can verify if a job is in a valid state to be picked.
- Search Threshold: A performance optimization that prevents the system from searching until the user has typed at least three characters, avoiding unnecessary database load.

2.4 Business Value

This feature streamlines the inventory process by enabling staff to quickly locate relevant service work orders directly within the "Stock Outgoing" workflow. By enforcing store-level and company-level security, it ensures that users only interact with data they are authorized to see, while the status-aware search helps prevent errors by ensuring only valid, pickable jobs are selected for outgoing stock.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-outgoings/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve the full details of a specific "Stock Outgoing" document. A Stock Outgoing document tracks items leaving your inventory. By using this feature, you can view the primary document information alongside all associated items (lines), related production tasks (work orders), and the original requests that triggered the outgoing movement (stock orders).

1.2 Step-by-Step Flow

1. Verification: The system identifies the user's company based on their current session to ensure they only access data they are authorized to see.
2. Document Lookup: The system searches for the specific Stock Outgoing document requested. If it cannot be found or does not belong to the user's company, an error is returned.
3. Data Gathering: Once the document is located, the system automatically collects all related information, including the list of items being moved, any linked work orders, and any associated stock orders.
4. Consolidation: The system combines the main document details with all the gathered related information into a single, comprehensive report.
5. Delivery: The complete package of information is presented to the user.

1.3 Key Concepts

- Stock Outgoing: A formal record representing inventory items that are being removed from your stock.
- Lines: The individual items or products included within a specific stock outgoing document.
- Work Orders: Production or maintenance tasks that are linked to the movement of these goods.
- Stock Orders: The original requests or source documents that initiated the need for this stock outgoing.
- Company Scope: A security measure that ensures users can only view documents that belong to their specific organization.
- Approval Status: Certain financial details (such as journal references) are kept blank until the document has been officially approved.

1.4 Business Value

This feature provides a "single source of truth" for inventory movements. By bundling the document with its related work and stock orders, staff can quickly audit why items were removed, what tasks were performed in relation to that movement, and which original orders triggered the process. This reduces the need to manually cross-reference multiple screens or reports, saving time and improving accuracy in inventory management.

2. Data

2.1 Overview

This feature provides a way to retrieve the full details of a specific "Stock Outgoing" record. A Stock Outgoing represents a movement of inventory leaving your facility. By using this feature, the system gathers the main document information along with all associated line items, linked work orders, and stock orders into a single, comprehensive view. This ensures that users have a complete picture of the inventory transaction and its origins.

2.2 Step-by-Step Flow

1. Verification: The system identifies the specific record requested and ensures it belongs to your company.
2. Document Retrieval: The system fetches the primary details of the Stock Outgoing record (such as its status and creation date).
3. Line Item Collection: The system gathers all individual items (lines) associated with that specific outgoing shipment.
4. Relationship Mapping: The system identifies and attaches any related Work Orders and Stock Orders that triggered or are linked to this movement.
5. Consolidation: The system combines all this information into one complete package and presents it to the user.

2.3 Key Concepts

- Stock Outgoing: A record tracking inventory that has been removed from your stock.
- Company Scoping: A security measure that ensures users can only view records belonging to their own organization.
- Linked Entities: Related documents (like Work Orders or Stock Orders) that provide context on why the inventory was moved.
- Source Line Information: Details attached to items that indicate if they were generated by another process; this helps the system determine if a record should be editable or if it is locked for review.

2.4 Business Value

This feature simplifies inventory management by providing a "single source of truth" for any outgoing shipment. Instead of searching through multiple areas of the system, staff can instantly see the full history and context of a stock movement. This transparency helps teams quickly verify why inventory was moved, identify which work orders were fulfilled, and understand the status of the transaction, ultimately leading to more accurate inventory reporting and faster troubleshooting.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/stock-outgoings/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to modify existing "draft" stock outgoing records. It provides a flexible way to update the source location or adjust the list of items being sent out. The system automatically handles the addition, modification, or removal of individual items within the request and ensures that all changes are validated against current inventory levels before saving.

1.2 Step-by-Step Flow

1. Verification: The system locates the requested stock outgoing record and confirms it is currently in "draft" status. If the record is already finalized, the update is rejected.
2. Header Update: If a new source location is provided, the system updates the record to reflect this change.
3. Item Processing: The system iterates through the list of items provided in the request:

* If an item is marked for removal, it is deleted from the record.

* If an item already exists, its details (such as product type or quantity) are updated.

* If an item is new, it is added to the record.

4. Validation: For every item, the system checks the current inventory at the selected source location. It confirms that the requested quantity is greater than zero and that sufficient stock is available.
5. Pricing: The system automatically calculates the unit cost for each item based on the current average cost found in the inventory.
6. Finalization: Once all items are validated and priced, the updated record is saved, and the system returns the complete, updated document.

1.3 Key Concepts

- Draft Status: A protective state that ensures only records that have not yet been finalized can be modified.
- Stock Outgoing Lines: The individual items or products included in a specific outgoing shipment.
- Inventory Validation: A safety check performed during the update to ensure you cannot ship more items than are currently available in your warehouse.
- Automated Pricing: The system automatically pulls the most recent cost data for products, removing the need for manual entry and ensuring financial accuracy.

1.4 Business Value

This feature streamlines inventory management by allowing users to correct or adjust outgoing shipments without having to delete and recreate them. By automating the validation of stock levels and the calculation of costs, the

system reduces the risk of human error, prevents shipments that exceed available inventory, and ensures that financial records remain accurate and up-to-date.

2. Data

2.1 Overview

This feature provides a way to modify "Stock Outgoing" documents that are currently in a draft state. It allows users to update general information about the outgoing stock request and manage the list of items (products) included in that request. The system ensures data integrity by validating that the requested items are available in stock and automatically calculating the correct costs based on current inventory data.

2.2 Step-by-Step Flow

1. Locate Document: The system searches for the specific draft document using the provided ID. If it cannot be found, the request is rejected.
2. Verify Status: The system checks if the document is still in "Draft" status. If it has already been processed or finalized, the update is blocked.
3. Apply Changes: The system processes the updates in a single batch:

* Updates the main document details (excluding the reference code).

* Adds new items, updates existing items, or removes items marked for deletion.

4. Validate and Price: The system performs a final check on all items:

* Confirms that all products exist and quantities are greater than zero.

* Verifies that the source location has enough stock to cover the requested quantities.

* Automatically updates the cost of each item based on the current average cost at the source location.

5. Finalize: If all checks pass, the changes are saved permanently, and the updated document is returned. If any check fails, the entire update is canceled to prevent errors.

2.3 Key Concepts

– Draft Status: A protective state that allows for editing; once a document moves out of this state, it can no longer be modified via this process.

– Stock Outgoing: A record representing a planned removal of inventory from a specific location.

– Transactional Update: A "all-or-nothing" approach where the system ensures that if any part of the update fails (e.g., insufficient stock), none of the changes are saved, keeping the data consistent.

–

Inventory Validation: A safety check that ensures you cannot request more items than are currently available at the chosen location.

- Automated Pricing: The system ignores manual cost inputs and instead pulls the most current average cost from the inventory records to ensure financial accuracy.

2.4 Business Value

This feature streamlines inventory management by allowing users to correct or adjust outgoing stock requests before they are finalized. By automating the cost calculation and enforcing strict stock availability checks, it reduces the risk of human error, prevents overselling of inventory, and ensures that financial reporting remains accurate and up-to-date.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/stock-outgoings/:id/status

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows staff to manage the lifecycle of a "Stock Outgoing" record by updating its status. Whether you need to finalize a shipment (confirm), stop a process (cancel), or restart a previously cancelled request (reset to draft), this tool ensures that every change is tracked and that inventory levels are respected before a confirmation is finalized.

1.2 Step-by-Step Flow

1. Request Identification: The system identifies the specific stock outgoing record you wish to update and the new status you want to apply.
2. Record Verification: The system checks if the requested record exists. If it cannot be found, the process stops.
3. Transition Validation: The system checks if the move from the current status to the new status is permitted (e.g., you cannot confirm a cancelled order without resetting it to draft first).
4. Inventory Check: If you are attempting to "confirm" an outgoing order, the system automatically verifies that you have enough items in stock for every product listed. If stock is insufficient, the system blocks the update and identifies exactly which product is missing and how much is currently available.
5. Final Update: If all checks pass, the system updates the record with the new status, records who made the change, and logs the exact time the update occurred.

1.3 Key Concepts

- Status Transition: The specific rules that dictate how an order can move between states (Draft, Confirmed, and Cancelled) to ensure business processes are followed correctly.
- Inventory Validation: A safety check performed during the "confirm" step to prevent outgoing orders that exceed current warehouse stock levels.
- Audit Trail: The automatic recording of the user who performed the update and the timestamp, ensuring accountability for every change made to an order.

1.4 Business Value

This feature provides a controlled and reliable way to manage inventory movement. By enforcing strict status transitions and performing real-time stock checks, it prevents human error—such as confirming an order for items that aren't in stock—and ensures that the warehouse team always has an accurate, up-to-date view of outgoing shipments. The built-in audit logging also provides transparency, making it easy to track who authorized changes to outgoing stock.

2. Data

2.1 Overview

This feature provides a controlled way to manage the lifecycle of a "Stock Outgoing" record. It allows authorized users to change the status of an outgoing stock request—moving it between Draft, Confirmed, and Cancelled states—while ensuring that the system maintains data integrity and prevents invalid business operations.

2.2 Step-by-Step Flow

1. Request Identification: The system locates the specific stock outgoing record based on the provided ID. If the record does not exist, the request is rejected.
2. Transition Validation: The system checks if the requested status change is permitted. For example, it allows moving from "Draft" to "Confirmed," but prevents illogical jumps (like moving directly from "Cancelled" to "Confirmed").
3. Stock Availability Check: If the user is attempting to "Confirm" the outgoing request, the system automatically verifies that there is enough stock on hand for every item in the request. If any item is out of stock, the request is blocked, and the system identifies exactly which products are insufficient.
4. Record Update: If all validations pass, the system updates the record with the new status, records the user who performed the action, and updates the timestamp.
5. Confirmation: The system returns the updated record to confirm the change was successful.

2.3 Key Concepts

- State Transition: The formal rules defining how a record can move from one status to another (e.g., Draft ’ Confirmed). This prevents accidental or unauthorized changes to the workflow.
- Stock Availability Check: A safety mechanism that ensures we do not confirm an outgoing shipment if we do not have enough physical inventory to fulfill it.
- Audit Trail: Every status change automatically logs the user responsible and the exact time the change occurred, ensuring accountability.
- Validation Errors: Specific feedback provided to the user when a request cannot be completed, such as identifying specific products that lack sufficient stock.

2.4 Business Value

- Operational Control: By enforcing strict status transitions, the system prevents errors in the warehouse workflow, ensuring that stock outgoing requests follow the company's defined business process.
-

Inventory Accuracy: The automated stock check prevents the confirmation of shipments that cannot be fulfilled, reducing the risk of backorders and customer dissatisfaction.

- Accountability: By tracking who updated a record and when, the business maintains a clear history of inventory movements, which is essential for auditing and troubleshooting.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/stock-outgoings/:id/approval

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a dedicated view for managers or approvers to review stock outgoing requests before they are finalized. When an approver opens a request, the system retrieves the document and automatically updates the financial and inventory data to reflect the most current information. This ensures that the approval decision is based on real-time costs and current warehouse stock levels rather than outdated figures from when the request was first created.

1.2 Step-by-Step Flow

1. Locate the Request: The system searches for the specific stock outgoing request using the provided ID.
2. Verify Status: The system checks if the request is in the "confirmed" state. If the request is still a draft or has already been approved, the system will block the request to prevent errors.
3. Retrieve Items: The system identifies all individual products listed in the outgoing request.
4. Fetch Current Financials: For every product in the request, the system looks up its current average cost.
5. Check Real-Time Inventory: The system checks the current quantity of each product available at the specific warehouse where the stock is being sent from.
6. Compile Data: The system combines the original request details with the updated cost and inventory figures.
7. Display for Approval: The final, updated document is presented to the user, ready for final review and approval.

1.3 Key Concepts

- Stock Outgoing: A formal request to move or remove items from inventory.
- Confirmed Status: A state indicating that the request is complete and ready for final management review.
- Average Cost: The most up-to-date financial value of a product, which may have changed since the request was initially drafted.
- Quantity on Hand: The actual amount of stock currently sitting in the warehouse at the exact moment the approval screen is viewed.
- COA Reversal ID: A reference code used to ensure that the financial accounting entries associated with the stock movement are correctly tracked and can be reversed if necessary.

1.4 Business Value

This feature eliminates the risk of approving stock movements based on stale data. By recalculating costs and checking current inventory levels at the moment of approval, the business ensures financial accuracy and prevents "overselling" or approving shipments for items that may no longer be available in the warehouse. This creates a

reliable audit trail and provides decision-makers with the confidence that the information they are approving is accurate and up-to-date.

2. Data

2.1 Overview

This feature provides a dedicated view for managers or approvers to review stock outgoing requests before they are finalized. It retrieves a "Confirmed" stock outgoing document and enriches it with real-time financial and inventory data. This ensures that the person approving the request sees the most current costs and stock levels, rather than outdated information that might have been captured when the request was first drafted.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user has permission to access the approval screen.
2. Document Validation: The system locates the requested stock outgoing document. It confirms the document is in the "Confirmed" state; if the document is still a draft or has already been approved, the system will block the request to prevent errors.
3. Data Enrichment: The system gathers the specific items (lines) associated with the outgoing request and pulls in two critical pieces of live data for each item:

* The current average cost of the product.

* The current quantity of that product available in the specific warehouse.

4. Response Generation: The system compiles the document details and the enriched item data into a single summary, which is then presented to the user for final approval.

2.3 Key Concepts

- Confirmed Status: A specific state for a stock outgoing request indicating it is ready for review but has not yet been finalized or processed.
- Current Average Cost: The most up-to-date valuation of a product, which may have changed since the initial request was created.
- Quantity on Hand: The real-time inventory count for a specific product at the source warehouse, ensuring the approver knows exactly what is available at the moment of approval.
- COA Reversal ID: A reference code used for accounting purposes, ensuring that the financial impact of the stock movement is correctly categorized.

2.4 Business Value

This feature improves financial accuracy and operational control. By forcing the system to pull "live" costs and inventory levels at the moment of approval, the business avoids discrepancies caused by price fluctuations or inventory changes that occur between the time a request is created and the time it is approved. This provides decision-makers with the reliable, up-to-date information needed to authorize stock movements confidently.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/stock-outgoings/:id/approve

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

The "Approve Stock Outgoing" feature is the final step in the inventory removal process. It transitions a "confirmed" stock outgoing document into an "approved" state. This action serves as the official trigger to permanently deduct items from your inventory and automatically generate the necessary financial accounting records (journal entries) to reflect the value of the goods removed.

1.2 Step-by-Step Flow

1. Verification: The system checks that the document exists and is currently in a "confirmed" status. If the document has already been approved or is not yet confirmed, the request is rejected to prevent duplicate processing.
2. Data Preparation: The system verifies that every line item in the outgoing request includes a designated reversal account code.
3. Inventory & Financial Processing: In a single, unified action, the system performs the following:

* Calculates the current average cost for each product.

* Deducts the items from the physical inventory.

* Creates a financial journal entry that debits the appropriate expense accounts and credits the inventory clearing account.

4. Finalization: The document is marked as "approved," the current date is recorded, the generated journal ID is linked to the document, and any provided notes are saved.

1.3 Key Concepts

- Stock Outgoing: A document representing a planned removal of items from inventory.
- Journal Entry: An automated accounting record that balances the books by debiting the specific expense account for the items removed and crediting the inventory value account.
- Atomicity: A safety feature ensuring that the inventory deduction and the financial journal posting happen together; if one part fails, the entire process is cancelled to prevent data mismatches.
- Reversal Account: A specific accounting code required to correctly categorize the financial impact of the stock removal.

1.4 Business Value

This feature ensures accuracy and consistency between your physical warehouse stock and your financial records. By automating the journal entry creation at the moment of approval, it eliminates manual data entry errors and

provides real-time visibility into inventory costs. Because the process is "atomic," you are guaranteed that your inventory levels will never be out of sync with your financial ledger.

2. Data

2.1 Overview

This feature provides a way to finalize a "Stock Outgoing" document in the Lumi ERP system. When a user approves a stock outgoing, the system performs a series of automated checks and updates to ensure that inventory levels are accurate and that the financial impact of the stock movement is correctly recorded in the company's journals. This process is designed to be "all-or-nothing," meaning if any part of the approval fails, the entire process is canceled to prevent data inconsistencies.

2.2 Step-by-Step Flow

1. Validation: The system checks if the document exists, is currently in a "Confirmed" state, and has not already been approved.
2. Inventory Check: The system verifies that there is enough stock available for every item listed in the outgoing request. It also ensures that every line item has the required accounting information (reversal accounts) attached.
3. Cost Calculation: The system updates each line item with the most current average cost to ensure financial accuracy.
4. Journal Posting: A new financial journal is created. For every item, the system records a debit to the specific account associated with that item and a corresponding credit to the general income account.
5. Finalization: The document status is updated to "Approved," the approval timestamp is recorded, and the stock is officially marked as moved out of inventory.

2.3 Key Concepts

- Transaction: A safety mechanism that ensures all steps (updating stock, creating journal entries, and finalizing the document) happen together. If one step fails, the system rolls back to the original state to prevent errors.
- Stock Outgoing: A document representing items leaving the inventory, which must be approved before it is considered final.
- Journal Entry: A record of the financial movement caused by the stock outgoing, ensuring that the inventory reduction is reflected in the company's accounting books.
- Average Cost: The current valuation of the inventory items, used to calculate the financial value of the stock being removed.

2.4 Business Value

This feature automates the transition from a "confirmed" request to a "finalized" inventory movement. By integrating stock verification with automatic journal posting, it eliminates manual data entry errors and ensures that the company's financial records are always in sync with physical inventory levels. This provides management with real-time visibility into both stock availability and the financial impact of outgoing goods.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/franchise-purchase-orders/:type

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a standardized way for the system to create new purchase orders for franchises. Depending on the business need, these orders can be categorized as either "internal" (e.g., transfers between company-owned locations) or "external" (e.g., orders placed with outside suppliers). The system ensures that all orders are properly validated, authorized, and recorded within the inventory management workflow.

1.2 Step-by-Step Flow

1. Request Submission: The user submits a request to create a purchase order, specifying whether it is an "internal" or "external" order type.
2. Authentication & Access Check: The system verifies the user's identity and ensures they have the necessary permissions to access the specific warehouses, stores, and suppliers involved in the order.
3. Validation: The system checks the order details, such as product availability, supplier eligibility, and quantity accuracy. If any information is incorrect or missing, the request is rejected.
4. Processing: Once validated, the system performs a secure "all-or-nothing" transaction. It creates the order record, adds the individual items, calculates the total order amount, and logs the initial "draft" status in the order history.
5. Confirmation: Upon successful creation, the system returns the details of the new purchase order, including its unique ID and current status.
6. Error Handling: If any part of the process fails (such as a duplicate request or invalid data), the system cancels the entire operation to prevent partial or corrupt data from being saved.

1.3 Key Concepts

- Internal vs. External Orders: A classification that determines the business rules applied to the order, such as which suppliers or products are eligible for selection.
- Transaction: A safety mechanism that ensures all parts of the order creation (the order header, the items, and the history log) are saved together. If one part fails, nothing is saved.
- Validation: A series of automated checks that ensure the order is logical and compliant with company policies before it is officially created.
- Draft Status: The initial state of a newly created purchase order, indicating it has been recorded but is not yet finalized or processed.
- Request UUID: A unique identifier used to prevent the same order from being accidentally submitted or processed twice.

1.4 Business Value

- Data Integrity: By using a transaction-based process, the system prevents incomplete or inaccurate orders from entering the inventory records.
- Operational Efficiency: Automating the validation of suppliers, products, and pricing reduces manual errors and speeds up the procurement process for franchise locations.
- Security: Strict access controls ensure that users can only create orders for locations and suppliers they are authorized to manage.
- Auditability: Every order is automatically linked to a creator and a workflow history, providing a clear trail of who created the order and when it was initiated.

2. Data

2.1 Overview

This feature allows the system to create new purchase orders for franchises, supporting both "internal" and "external" order types. When a user submits a purchase order, the system performs a series of automated checks to ensure the data is accurate and valid before saving it. The entire process is handled as a single, secure transaction, meaning that if any part of the process fails, the system will automatically cancel the entire operation to prevent incomplete or corrupted data.

2.2 Step-by-Step Flow

1. Initiation: The system starts a secure transaction to ensure data consistency.
2. Validation: The system checks the request against business rules (e.g., verifying that the supplier, warehouse, and products exist and are eligible for the chosen order type).
3. Order Creation: The primary purchase order record is created in the system with an initial status of "draft."
4. Item Processing: The individual products requested are added to the order, including their specific quantities and pricing.
5. Total Calculation: The system automatically calculates the total cost of the order based on the items provided and updates the order record.
6. Workflow Logging: The system records the initial "draft" status in the order's history log.
7. Completion: The transaction is finalized (committed), and the system returns the full details of the newly created order to the user.

2.3 Key Concepts

-

Transaction: A "all-or-nothing" safety mechanism. If any step in the creation process fails, the system rolls back to the state before the request started, ensuring no partial or broken orders are saved.

- Validation: A series of automated checks that ensure the request is legitimate, such as confirming that a supplier is allowed to fulfill the specific type of order requested.
- Draft State: The initial status assigned to a new order, indicating it has been created but is not yet finalized or processed.
- Request UUID: A unique identifier for each request that prevents the same order from being accidentally submitted or processed twice.

2.4 Business Value

- Data Integrity: By using a transaction-based approach, the system guarantees that purchase orders are always complete and accurate, eliminating the risk of "orphaned" items or missing order totals.
- Operational Efficiency: Automated validation and calculation reduce manual data entry errors and ensure that only valid, authorized orders are entered into the system.
- Flexibility: The system seamlessly handles both internal and external franchise orders, allowing the business to manage different supply chain relationships through a single, unified interface.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/franchise-purchase-orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows the system to officially record a new purchase order initiated by a franchise. It acts as a digital bridge between a warehouse, a specific store, and a supplier, ensuring that inventory movement requests are captured accurately within the Lumi ERP system.

1.2 Step-by-Step Flow

1. Security Verification: The system first checks if the user is logged in and possesses the necessary permissions to create purchase orders. If not, the request is blocked.
2. Data Validation: The system verifies that the request includes all essential information: where the goods are coming from (warehouse), where they are going (store), and which supplier is involved.
3. Order Creation: Once validated, the system generates a unique identifier for the order, sets the initial status to "Pending," and records the timestamp and the user who created it.
4. Database Storage: The completed order details are saved into the system's permanent records.
5. Confirmation: The system returns the full details of the newly created order to the user as confirmation that the process was successful.

1.3 Key Concepts

- Franchise Purchase Order: A formal request document that tracks the movement of inventory from a central warehouse to a specific franchise store.
- Authentication: The process of verifying the identity of the user to ensure they are a recognized member of the system.
- Authorization: The process of checking if a verified user has the specific "permission" required to perform the action of creating an order.
- Pending Status: The default state assigned to a new order, indicating that it has been successfully created but has not yet been processed or fulfilled.

1.4 Business Value

- Operational Efficiency: Automates the manual entry of franchise orders, reducing the risk of human error and speeding up the supply chain process.
- Inventory Accuracy: By requiring specific warehouse and store identifiers, the system ensures that inventory levels are tracked correctly across all locations.
-

Accountability: Every order is linked to the user who created it and includes a precise timestamp, providing a clear audit trail for management.

- Standardization: Enforces a consistent process for all franchise locations, ensuring that no order is created without the necessary supplier and location details.

2. Data

2.1 Overview

This feature enables the system to officially record a new franchise purchase order. It acts as a digital bridge between a warehouse, a specific store, and a supplier, ensuring that all inventory movement requests are tracked accurately within the Lumi ERP system.

2.2 Step-by-Step Flow

1. Validation: The system first checks that the warehouse, store, and supplier identified in the request actually exist in our records. If any of these are missing or invalid, the request is rejected.
2. Order Creation: Once validated, the system generates a unique identifier for the order and assigns it a "Pending" status.
3. Data Logging: The system automatically records the exact time the order was created and identifies which authorized user initiated the request.
4. Persistence: The completed order details are saved into the central database.
5. Confirmation: The system returns the finalized order record to the user as confirmation that the process was successful.

2.3 Key Concepts

- Franchise Purchase Order: A formal request document that tracks inventory being moved from a warehouse to a specific franchise store via a designated supplier.
- Validation: A safety check performed by the system to ensure that all parties involved (warehouse, store, and supplier) are recognized entities before an order is processed.
- Pending Status: The initial state of a new order, indicating that it has been successfully created but has not yet been fulfilled or completed.
- Audit Trail: The automatic recording of "who" created the order and "when," which ensures accountability and transparency for all inventory transactions.

2.4 Business Value

-

Data Integrity: By validating references before saving, the system prevents "orphan" orders or errors caused by incorrect store or warehouse information.

- Operational Efficiency: Automating the creation of these records reduces manual data entry and ensures that all franchise locations have a standardized way to request stock.
- Accountability: Every order is linked to an authenticated user and a timestamp, providing a clear history for inventory audits and troubleshooting.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/franchise-purchase-orders/:id/reset

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature allows authorized users to "reset" a franchise purchase order that has been previously cancelled. By triggering this action, the system moves the order back into a "draft" status, allowing it to be edited or processed again without needing to create an entirely new order from scratch.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided order identifier is formatted correctly.
2. Authorization: The system verifies that the person making the request has the necessary administrative or managerial permissions.
3. Verification: The system searches for the specific purchase order to ensure it exists and belongs to the user's company.
4. Status Check: The system confirms the order is currently in a "cancelled" state. If the order is in any other state, the reset request is rejected.
5. Update: The system updates the order status to "draft" and records the current time as the last update.
6. Confirmation: The system returns the updated order details to confirm the process was successful.

1.3 Key Concepts

- Franchise Purchase Order: A formal request for goods or services within the franchise network.
- Workflow State: The current stage of an order in its lifecycle (e.g., "cancelled" or "draft").
- Reset: A corrective action that reverts a cancelled order to a draft state so it can be modified or resubmitted.
- Authorization: A security check to ensure only designated staff (Admins or Managers) can modify order statuses.

1.4 Business Value

This feature improves operational efficiency by reducing manual rework. Instead of forcing staff to discard a cancelled order and manually re-enter all the data for a new one, they can simply reset the existing order. This saves time, reduces the risk of data entry errors, and maintains a clean audit trail for franchise procurement activities.

2. Data

2.1 Overview

This feature allows authorized users to "reopen" a franchise purchase order that has been previously cancelled. By resetting the order status back to "draft," users can make necessary adjustments or corrections to an order that was previously discarded, rather than having to create a new order from scratch.

2.2 Step-by-Step Flow

1. Verification: The system confirms the user has the appropriate permissions (Admin or Manager) and that the requested purchase order exists within their company.
2. Status Check: The system checks the current status of the purchase order.
3. Validation: If the order is currently marked as "cancelled," the system proceeds to update the status. If the order is in any other state, the request is rejected to prevent accidental changes to active or completed orders.
4. Update: The system updates the order status to "draft" and records the current time as the last update.
5. Confirmation: The system returns the updated order details to the user.

2.3 Key Concepts

- Draft State: A status indicating that an order is currently being prepared or edited and is not yet finalized or submitted.
- Cancelled State: A terminal status for an order that has been voided; this is the only state from which an order can be "reset."
- Atomic Update: A safety mechanism that ensures the status change only happens if the order is currently in the expected "cancelled" state, preventing conflicts if the order status changed while the request was being processed.
- Company Context: A security boundary that ensures users can only modify purchase orders that belong to their specific organization.

2.4 Business Value

This feature improves operational efficiency by providing a "recovery" path for cancelled orders. It reduces administrative overhead by eliminating the need to manually recreate purchase orders that were cancelled in error or require minor modifications, ensuring that data remains accurate and workflows remain flexible.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/franchise-purchase-orders/:id/place

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature allows authorized users to officially "place" a franchise purchase order within the Lumi ERP system. By triggering this action, an order that has already been confirmed by the store moves into the "placed" status, which formally records the date and time the order was finalized.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided order identifier is formatted correctly.
2. Verification: The system locates the order and confirms it belongs to the user's company.
3. Authorization: The system verifies that the person performing the action has the necessary permissions (specifically, an Admin or Manager role).
4. Status Check: The system ensures the order is currently in the "store confirmed" state. If the order is in any other state, the action is blocked to prevent errors.
5. Finalization: If all checks pass, the system updates the order status to "placed," records the current timestamp, and confirms the update is complete.

1.3 Key Concepts

- Franchise Purchase Order: A formal request for goods or services initiated by a franchise location within the ERP.
- Workflow State: The current stage of an order in its lifecycle (e.g., "store confirmed" vs. "placed"). This ensures orders follow a logical sequence.
- Authorization: A security measure that restricts specific actions to users with appropriate administrative or managerial roles.
- Conflict: A scenario where an action cannot be completed because the order is not in the correct state to be moved forward.

1.4 Business Value

This feature provides a controlled, secure way to finalize procurement activities. By enforcing strict state transitions and authorization checks, it ensures that only authorized personnel can place orders and that orders cannot be accidentally or prematurely moved to a "placed" status. This maintains data integrity and provides an accurate audit trail of when exactly an order was finalized.

2. Data

2.1 Overview

This feature allows users to officially "place" a franchise purchase order within the Lumi ERP system. By triggering this action, a purchase order that has already been confirmed by a store is moved to a "placed" status, which formally records the date and time the order was finalized.

2.2 Step-by-Step Flow

1. Verification: The system locates the specific purchase order requested and confirms that it belongs to the company currently logged into the system.
2. Validation: The system checks the current status of the order. It will only proceed if the order is in the "store_confirmed" state. If the order is in any other state, the request is rejected to prevent accidental or duplicate processing.
3. Finalization: Once validated, the system updates the order status to "placed" and automatically stamps the record with the current date and time.

2.3 Key Concepts

- Franchise Purchase Order: A formal request for goods or services initiated by a franchise location.
- Workflow State: The current stage of an order in its lifecycle (e.g., "store_confirmed" vs. "placed").
- State Transition: The process of moving an order from one status to another, ensuring that business rules are followed at every step.
- Timestamping: The automatic recording of the exact moment an action occurs, providing an audit trail for when an order was officially placed.

2.4 Business Value

This feature ensures data integrity and operational consistency. By enforcing a strict workflow, the system prevents users from placing orders that haven't been properly confirmed by the store. Additionally, by automatically capturing the "placed at" timestamp, the business gains accurate reporting on order lead times and fulfillment cycles, which is essential for inventory management and supply chain planning.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/inventory/stock-return/new

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows franchise users to initiate a formal request to return inventory items. When a user submits a return request, the system validates their identity, ensures the inventory item exists, and confirms that a return hasn't already been processed for that specific item. Once validated, the system creates a new return record in a "draft" status, allowing for further processing or review.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to create stock returns.
2. Data Validation: The system checks that the request includes all required information (the item ID, the quantity, and the reason for the return) and ensures the quantity is a valid, positive number.
3. Item Verification: The system confirms that the inventory item being returned actually exists in the database.
4. Conflict Check: The system checks if a return request for this specific item already exists to prevent duplicate entries.
5. Record Creation: If all checks pass, the system creates the return record, assigns it a "draft" status, and records who created it and when.

1.3 Key Concepts

- Stock Return: A formal request to send inventory back, which begins in a "draft" state to allow for administrative oversight.
- Authentication & Authorization: Security measures that ensure only verified users with the correct job roles can initiate returns.
- Validation: The process of ensuring the information provided is complete and accurate before the system attempts to save it.
- Conflict Resolution: A safeguard that prevents the system from creating multiple return requests for the same item, ensuring data integrity.

1.4 Business Value

This feature streamlines the inventory management process for franchises by providing a standardized, digital way to track returns. By automating the validation and conflict-checking steps, the system reduces manual errors, prevents duplicate return requests, and ensures that all returns are properly documented and attributed to the correct user from the moment they are created.

2. Data

2.1 Overview

This feature provides a standardized way for franchises to initiate a return of inventory items. When a user submits a request to return stock, the system automatically validates the request to ensure data integrity and prevents duplicate processing. All new return requests are initially saved in a "draft" status, allowing for further review or processing before they are finalized.

2.2 Step-by-Step Flow

1. Authentication and Authorization Check: The system verifies that the user is logged in and has the necessary permissions to initiate a stock return.
2. Data Validation: The system checks the incoming request to ensure all required information (such as item details and quantity) is present and correctly formatted.
3. Inventory Verification: The system confirms that the specific item being returned actually exists in the inventory database.
4. Duplicate Check: The system checks if there is already an active (non-completed) return request for that specific item to prevent double-processing.
5. Record Creation: If all checks pass, the system creates a new return record, assigns it a "draft" status, and records the timestamp and the user who initiated the request.
6. Confirmation: The system returns the details of the newly created draft record to the user.

2.3 Key Concepts

- Draft Status: The initial state of a return request, indicating that it has been created but is not yet finalized or completed.
- Inventory Item: The specific product or stock unit being referenced for the return.
- Validation: The process of ensuring that the request is complete and that the items involved are valid, preventing errors in the system.
- Conflict Prevention: A safeguard that stops the system from creating multiple active return requests for the same item, ensuring inventory records remain accurate.

2.4 Business Value

This feature streamlines the franchise return process by automating the initial validation and record-keeping steps. By enforcing strict checks—such as verifying item existence and preventing duplicate requests—the system

reduces manual administrative work, minimizes data entry errors, and ensures that inventory levels remain accurate and reliable throughout the return lifecycle.

BUSINESS REQUIREMENTS DOCUMENT

POST /franchise_purchase_returns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows the system to process returns of goods from a franchise back to a supplier. When a franchise needs to return items originally purchased through a specific purchase order, this tool records the return details, validates the quantities against the original order, and ensures that each purchase order is only processed for a return once.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to initiate a franchise return.
2. Data Validation: The system checks that all required information (such as the source store, supplier, original purchase order, and the list of items) is provided.
3. Order Verification: The system confirms that the referenced purchase order actually exists in the database.
4. Duplicate Prevention: The system checks if a return has already been created for that specific purchase order to prevent double-processing.
5. Quantity Validation: The system reviews each item being returned to ensure the quantity does not exceed the amount originally purchased or allowed for return.
6. Record Creation: If all checks pass, the system saves the return header information and the individual item details into the database as a single, secure transaction.
7. Confirmation: Upon successful saving, the system returns a confirmation message containing the details of the newly created return record.

1.3 Key Concepts

- Franchise Purchase Return: A formal record indicating that items previously bought by a franchise are being sent back to a supplier.
- Purchase Order Reference: The unique identifier linking the return to the original transaction, ensuring the return is valid and traceable.
- Transaction: A safety mechanism that ensures all parts of the return (the header and the list of items) are saved together; if any part fails, nothing is saved, preventing data errors.
- Validation: The process of checking that the return request is logical—for example, ensuring you cannot return more items than were originally purchased.

1.4 Business Value

-

Inventory Accuracy: By linking returns directly to original purchase orders, the system maintains an accurate count of stock levels across the franchise network.

- Fraud and Error Prevention: Automated checks prevent duplicate returns for the same order and ensure that return quantities remain within authorized limits.
- Operational Efficiency: Standardizing the return process reduces manual oversight and provides a clear audit trail for both the franchise and the supplier.

2. Data

2.1 Overview

The `POST /franchisepurchasereturns` feature allows users to formally record the return of inventory items that were originally purchased through a franchise purchase order. This process ensures that returns are tracked accurately against the original order, preventing errors such as duplicate returns or returning more items than were originally purchased.

2.2 Step-by-Step Flow

1. Order Verification: The system checks if the original franchise purchase order exists. If it cannot be found, the request is rejected.
2. Duplicate Check: The system verifies that a return has not already been processed for that specific purchase order to prevent double-counting.
3. Quantity Validation: The system compares the requested return quantity for each item against the maximum allowed return quantity (based on the original order). If any item exceeds this limit, the request is rejected.
4. Record Creation: Once all validations pass, the system creates a new "Stock Return" header record, which includes details like the store location, supplier, and reference information.
5. Item Processing: The system saves the individual items being returned, linking them to the newly created return record.

2.3 Key Concepts

- Franchise Purchase Order: The original document representing the goods received by the franchise, which serves as the foundation for any subsequent returns.
- Maximum Return Quantity: A safety limit derived from the original order that prevents users from returning more stock than was originally purchased.
- Transaction: A safety mechanism that ensures the entire return process is treated as a single unit of work; if any part of the process fails (e.g., saving an item), the entire operation is canceled to keep the data consistent.

- Stock Return Header: The primary record that summarizes the return, containing administrative details like the document number, notes, and the parties involved.

2.4 Business Value

This feature provides a controlled and auditable way to manage inventory returns. By enforcing strict validation against original purchase orders, it prevents inventory discrepancies and financial errors. It also streamlines operations by automating document numbering and ensuring that all returns are properly linked to their source, which simplifies reporting and reconciliation for franchise accounting.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/franchise-purchase-return

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for authorized users to retrieve a list of purchase returns associated with a specific franchise. It allows users to narrow down results by selecting a specific date range and supports paginated viewing to ensure the system remains fast and easy to navigate when dealing with large amounts of data.

1.2 Step-by-Step Flow

1. Authentication: The system verifies the user's identity to ensure they are logged in.
2. Request Validation: The system checks that the required franchise identifier is provided in the request.
3. Authorization: The system confirms that the authenticated user has the necessary permissions to view data for the requested franchise.
4. Data Retrieval: The system searches the database for purchase returns matching the franchise ID and any optional date filters provided.
5. Response: The system returns the requested list of records. If no records are found or if any errors occur during the process, the system provides an appropriate status message.

1.3 Key Concepts

- Franchise Purchase Return: A record of items returned by a franchise, including details like the return date, total amount, and current status.
- Date Filtering: The ability to limit the search results to a specific timeframe (e.g., returns made between two specific dates).
- Pagination: A method of breaking large lists of data into smaller, manageable pages (e.g., 20 records per page) to improve performance and readability.
- Authorization: A security check that ensures users can only access data for franchises they are officially permitted to manage or view.

1.4 Business Value

This feature enables franchise managers and administrators to maintain accurate inventory and financial records. By providing a filtered, paginated view of purchase returns, it simplifies the process of auditing returns, tracking financial adjustments, and resolving discrepancies between the franchise and the central inventory system.

2. Data

2.1 Overview

The "Franchise Purchase Return" feature allows authorized users to retrieve a list of purchase returns associated with a specific franchise. This tool is designed to help businesses track returned inventory items, providing visibility into return history through flexible search and filtering options.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view purchase returns for a specific franchise.
2. Verification: The system first confirms that the requested franchise exists in the database. If the franchise cannot be found, the system returns an error.
3. Filtering: The system applies any requested filters, such as a specific date range (start and end dates), to narrow down the results.
4. Pagination: To ensure the system remains fast and easy to navigate, the results are broken into "pages." The system calculates which specific slice of data to show based on the requested page number and the limit of items per page.
5. Sorting: The retrieved records are automatically sorted by the return date, with the most recent returns appearing first.
6. Data Delivery: The system returns the final list of purchase return records to the user.

2.3 Key Concepts

– Pagination: A method of splitting a large list of records into smaller, manageable chunks (pages) to improve performance and readability.

– Filtering: The ability to narrow down search results based on specific criteria, such as a date range, to find relevant information quickly.

– Data Integrity: The process of verifying that a franchise exists before attempting to pull its records, ensuring the system provides accurate feedback if an ID is incorrect.

– Sorting: Organizing the data in a specific order (in this case, by date) so that the most relevant or recent information is prioritized.

2.4 Business Value

This feature provides essential transparency into inventory management. By enabling franchises to easily pull and filter their return history, businesses can:

* Improve Accuracy: Quickly reconcile return records against inventory levels.

* Enhance Reporting: Easily generate data for specific time periods to support financial or operational audits.

* Optimize Performance: By using pagination, the system ensures that even franchises with a high volume of returns can access their data quickly without system slowdowns.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Order Table JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Franchise Purchase Order feature provides a structured way for franchise stores to manage their procurement process. It allows stores to create and track orders for products sourced from either external suppliers or the franchisor. The system handles both the high-level order information (the "header") and the specific product details (the "line items") separately, ensuring that the application remains responsive even when orders contain many items.

1.2 Step-by-Step Flow

1. Order Creation & Management: A user initiates a purchase order, which is stored as a header record. This record tracks essential details like the store, supplier, order type, and the current workflow status (e.g., draft, sent, received).
2. Adding Items: Individual products are added to the order as line items. Each item tracks the quantity ordered, the price, and any applicable discounts.
3. Dynamic Calculations: The system does not store total order amounts in the database. Instead, it calculates subtotals, discounts, taxes, and final totals in real-time based on the current line items. This ensures that financial data is always accurate and reflects the most recent updates.
4. Retrieving Lists: When viewing a list of orders, the system provides a summary that includes calculated totals and status information, allowing users to filter by criteria such as store, supplier, or workflow state.
5. Viewing Details: When a user selects a specific order, the system fetches the header information and the associated line items. The line items are retrieved separately, allowing the system to handle large orders efficiently through pagination.

1.3 Key Concepts

- Header Record: The main purchase order document that contains general information like the store, supplier, and overall status.
- Line Items: The individual product rows within an order, which track specific quantities, prices, and discounts for each item.
- Workflow State: The current stage of the order in the procurement lifecycle, such as "Draft," "Sent," or "Received."
- Real-time Calculation: The process of computing financial totals (like subtotal and tax) on-the-fly whenever an order is viewed, rather than saving these values permanently.
- Pagination: A method used to break large lists of orders or line items into smaller, manageable pages to improve system performance.

1.4 Business Value

- Operational Efficiency: By separating the order header from the line items, the system remains fast and responsive, even for complex orders with many products.
- Data Accuracy: Because financial totals are calculated dynamically from the line items, the risk of discrepancies between the order summary and the individual items is eliminated.
- Flexibility: The system supports different procurement scenarios—such as internal orders from a warehouse or external orders from third-party suppliers—within a single, unified interface.
- Improved Visibility: With robust filtering and status tracking, franchise managers can easily monitor the progress of their orders from creation to final receipt.

BUSINESS REQUIREMENTS DOCUMENT

Inventory Store Stock JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Inventory Store Stock feature provides a structured way to manage and track inventory movements between warehouses and stores within the Lumi ERP system. It covers three primary operational areas: Stock Orders (transferring goods), Stock Returns (sending items back from stores), and Stock Opnames (physical stock counts and adjustments). This system ensures that inventory data remains accurate, auditable, and synchronized across all locations.

1.2 Step-by-Step Flow

1. Stock Orders:

* Users initiate a transfer request from a warehouse to a store.
* The system tracks the order through various stages: Draft, Confirmed, Sent, and Received.
* The system maintains a detailed list of items per order, including quantities ordered, sent, and received, along with any specific remarks from the warehouse or store.

2. Stock Returns:

* Stores can initiate a return document to send items back to a warehouse or supplier.
* The system tracks the return from creation through approval, ensuring that returned stock is properly accounted for in the destination location.

3. Stock Opnames (Physical Counts):

* Stores perform physical stock counts to verify system records against actual inventory.
* The system generates a document that compares "system quantity" with "counted quantity."
* Any discrepancies (variance) are calculated, and the system supports a workflow to confirm and approve these adjustments to reconcile the inventory.

1.3 Key Concepts

- Stock Order: A formal request to move inventory from a warehouse to a specific store.
- Stock Return: A document used to process the movement of goods from a store back to a warehouse or supplier.
- Stock Opname: A physical inventory audit process used to identify and correct discrepancies between recorded stock and actual stock on hand.
- Workflow State: The current status of a document (e.g., Draft, Confirmed, Approved, Completed, Cancelled), which dictates what actions can be performed next.
-

Source Type: Identifies the origin of a stock request, such as a standard stock order, a sale, or a service work order, allowing the system to link inventory movements to specific business activities.

– Variance: The difference between the expected system quantity and the actual counted quantity during a stock opname.

1.4 Business Value

* Inventory Accuracy: By formalizing stock counts (Opnames) and transfers (Orders/Returns), the system minimizes discrepancies and ensures that store stock levels are always reliable.

* Operational Efficiency: The automated tracking of document lifecycles reduces manual paperwork and provides clear visibility into where inventory is at any given time.

* Auditability: Every movement and adjustment is tied to a specific document, user, and timestamp, creating a clear trail for financial and operational reporting.

* Seamless Integration: By linking stock orders to other business processes (like service orders or sales), the system ensures that inventory consumption is automatically reflected in the ERP, preventing stockouts and overstocking.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Return List JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a structured way to retrieve and display a list of "Franchise Purchase Returns" within the Lumi ERP system. It allows users to view, filter, and search through return records specifically related to franchise operations. The system automatically organizes this data, resolves relevant names (like stores, suppliers, and warehouses), and provides pagination to ensure the list remains easy to navigate.

1.2 Step-by-Step Flow

1. Request Parameters: The system receives a request containing optional filters, such as the current status of the return, specific store or supplier IDs, date ranges, or partial reference codes for the return or the original order.
2. Data Retrieval: The system queries the database, specifically looking for records marked as franchise-related returns.
3. Information Enrichment: As it gathers the data, the system automatically looks up and attaches human-readable names for the locations (stores and warehouses), the supplier involved, the original purchase order, and the user who created the record.
4. Sorting and Pagination: The results are sorted by the date they were created (newest first). The system also calculates the total number of matching records to support page-by-page navigation.
5. Response Delivery: The system returns a clean, organized list of return records along with the pagination details, ready to be displayed in the user interface.

1.3 Key Concepts

- Franchise Purchase Return: A record representing stock being returned from a franchise location, either back to a supplier or to an internal warehouse.
- Workflow State: The current status of a return (e.g., Draft, Sent, Approved, or Cancelled), which helps users track the progress of the return process.
- Reference Code: A unique identifier for the return, used to quickly locate specific documents.
- Pagination: A method of breaking a large list of records into smaller, manageable chunks (e.g., 20 items per page) to improve performance and readability.
- Entity Resolution: The process of automatically matching internal system IDs (like a store ID) to their actual names (like "Downtown Store") so the list is meaningful to the user.

1.4 Business Value

- Operational Visibility: Provides franchise managers and staff with a clear, searchable view of all active and historical returns, reducing the time spent searching for specific documents.

- Improved Accuracy: By automatically resolving names for stores, suppliers, and warehouses, the system ensures that users see consistent and correct information without needing to cross-reference other reports.
- Efficient Workflow Management: With built-in filtering by status and date, users can quickly identify returns that require immediate attention, such as those waiting for approval or those that have been recently sent.
- Scalability: The pagination logic ensures that the system remains fast and responsive, even as the number of franchise return records grows over time.

BUSINESS REQUIREMENTS DOCUMENT

Discrepancy Stock JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Discrepancy Stock" feature allows users to report and track inventory discrepancies at the store level. This system provides a structured way to document items that do not match expected stock levels, enabling better oversight and resolution of inventory issues. The feature includes both a list view for monitoring existing reports and a creation form for submitting new ones.

1.2 Step-by-Step Flow

1. Submission: A user fills out a "Discrepancy Stock" form, selecting the store (entity) and adding one or more product lines, each with a counted quantity and optional notes.
2. Validation & Processing: The system receives the request, validates the data, and automatically assigns system-generated details like the document reference code, the current date, and the initial "draft" status.
3. Storage: The system saves the report header (the store and document info) and the individual product items into the database.
4. Retrieval: When viewing the "Store" tab, the system retrieves a list of these reports. It joins the report data with product and store information to provide a complete view.
5. Display: The system presents the data in a paginated list, allowing users to filter by date, product, document code, or status (e.g., draft, responded, or done).

1.3 Key Concepts

- Discrepancy Stock: A formal record of a difference between recorded inventory and actual physical stock.
- Entity: The specific store location where the discrepancy was identified.
- Item-Level Reporting: Each report is broken down by individual product lines, meaning a single report can contain multiple products, each tracked as its own line item.
- Idempotency Token: A unique identifier included with the submission to prevent duplicate reports if a user accidentally clicks "submit" multiple times.
- AASM State: The workflow status of a report, which tracks its lifecycle from an initial "draft" to "responded" and finally "done."
- Pagination: A method of organizing large lists of reports into smaller, manageable pages (using limit and offset) to ensure the application remains fast and responsive.

1.4 Business Value

-

Improved Inventory Accuracy: By providing a standardized process for reporting discrepancies, the business can identify and address stock issues more quickly.

- Operational Transparency: The system maintains a clear audit trail of who created a report, when it was created, and its current status, ensuring accountability.
- Efficient Workflow: The automated generation of reference codes and status tracking reduces manual administrative work, allowing store staff to focus on resolving the actual inventory issues.
- Better Decision Making: With the ability to filter and search through historical discrepancy data, management can identify recurring stock issues at specific stores or with specific products.

2. LOGIC

2.1 Overview

The Discrepancy Stock feature allows users to record and track inventory differences at specific store locations. When a user identifies a mismatch between physical stock and system records, they can create a "Discrepancy Report." This report acts as a formal document that captures the details of the items involved, the store where the issue occurred, and any relevant notes. The system automatically generates a unique reference code for each report to ensure easy tracking and auditing.

2.2 Step-by-Step Flow

1. Entity Selection: The user selects the relevant store from a list of active locations.
2. Product Search: The user searches for products to add to the report using a lookup tool that filters by SKU or product name.
3. Report Creation: The user submits the report, which includes the store ID, the list of products, the counted quantities, and any optional notes.
4. Automatic Numbering: Upon submission, the system automatically generates a unique document reference code (e.g., DISC/STORE-CODE/SEQUENCE) to identify the report.
5. Data Validation & Storage: The system saves the report header and all individual product lines in a single transaction, ensuring that the data is consistent and complete.
6. Review: Users can view a list of all discrepancy reports or drill down into the details of a specific report to see its current status and history.

2.3 Key Concepts

- Discrepancy Report: A digital record used to document inventory mismatches at a store.
-

Reference Code: A unique, system-generated identifier for each report, formatted to include the store code and a sequential number.

- Idempotency Token: A safety mechanism that prevents the system from creating duplicate reports if a user accidentally clicks the "submit" button multiple times.
- Draft Status: The initial state of a newly created report, indicating it is ready for review or further action.
- Product Lookup: A search tool that helps users quickly find and select the correct items to include in their discrepancy report.

2.4 Business Value

- Improved Inventory Accuracy: Provides a structured way to identify and document stock discrepancies, leading to better inventory management.
- Operational Accountability: By tracking who created or updated a report and assigning a unique reference code, the business maintains a clear audit trail for all stock adjustments.
- Efficiency: The automated numbering system and product lookup tool reduce manual data entry errors and speed up the reporting process for store staff.
- Data Integrity: The use of transactional saving ensures that reports are never partially saved, preventing incomplete or corrupted data from entering the system.

BUSINESS REQUIREMENTS DOCUMENT

Stock Transfer JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Stock Transfer feature provides a structured way to move inventory between different locations (such as stores or warehouses) within your organization. It manages the entire lifecycle of a transfer, from the initial request and approval to the final receipt of goods, ensuring that inventory records and accounting journals remain accurate throughout the process.

1.2 Step-by-Step Flow

1. Creation: A user initiates a transfer by selecting the source and destination locations, adding products, and specifying quantities. The system automatically captures the current stock levels and costs to ensure accuracy.
2. Drafting: The transfer is saved as a "draft," allowing for review before any official movement occurs.
3. Workflow Progression: Authorized users move the transfer through various stages (Confirm, Approve, Send, and Receive). Each step is time-stamped and linked to the specific user who performed the action.
4. Finalization: When the goods are marked as "received," the system updates the destination inventory and automatically generates the necessary accounting journal entries to reflect the change in value.
5. Monitoring: Users can view a list of all transfers with search and filter capabilities, or drill down into the details of a specific transfer to see its full history and status.

1.3 Key Concepts

- Workflow State: The current status of a transfer (e.g., Draft, Confirmed, Approved, Sent, Received, or Cancelled), which determines what actions can be taken next.
- Idempotency: A safety mechanism that prevents the same transfer from being created or processed twice if a user accidentally clicks a button multiple times.
- Snapshotting: The system automatically records the stock levels and costs at the moment of creation, preventing errors caused by outdated information.
- Accounting Journal: An automated record created during the "Send" and "Receive" phases to ensure the financial value of the inventory is correctly tracked in your books.
- Location Types: The system supports transfers between different types of entities, including stores, warehouses, and the company itself.

1.4 Business Value

- Data Integrity: By snapshotting costs and quantities at the time of creation, the system prevents discrepancies caused by stale data.
-

Accountability: Every stage of the transfer process is tracked, providing a clear audit trail of who initiated, approved, and completed each movement.

- Operational Efficiency: Automated journal entries reduce manual accounting work and minimize the risk of human error during inventory movements.
- Visibility: The list and detail views provide real-time insight into the status of all inventory in transit, helping managers make better-informed decisions about stock availability.

BUSINESS REQUIREMENTS DOCUMENT

Stock Reservation JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Stock Reservation feature allows users to search and retrieve a list of inventory reservations within the Lumi ERP system. This tool provides visibility into which products have been set aside, the quantities involved, and the specific store locations associated with those reservations. Users can filter these results by date range, product details, or store location to quickly find the information they need.

1.2 Step-by-Step Flow

1. Input Filtering: The system receives search criteria from the user, such as a specific date range, product name, SKU, or store location.
2. Data Retrieval: The system searches the inventory database for all records that match the provided filters.
3. Data Processing: The system cleans and organizes the retrieved information to ensure it is consistent and easy to read.
4. Formatting: The system formats the final list of reservations into a standardized structure, ensuring that essential details like the reservation date, product name, and quantity are clearly presented.
5. Display: The final, organized list of reservations is returned to the user interface for viewing.

1.3 Key Concepts

- Stock Reservation: A record indicating that a specific quantity of a product has been set aside or allocated for a particular purpose or order.
- Filters: Search parameters that allow users to narrow down large lists of data to find specific records (e.g., looking for reservations only for a specific store or date).
- SKU (Stock Keeping Unit): A unique identifier used to track individual products within the inventory.
- Sanitization: A process that ensures the search information provided by the user is safe and correctly formatted before the system attempts to use it to look up data.

1.4 Business Value

This feature improves inventory management by providing real-time transparency into reserved stock. By allowing staff to quickly filter and locate reservation records, the business can:

- Reduce errors in order fulfillment by confirming exactly what stock is available versus what is already spoken for.
- Improve customer service by providing accurate, up-to-date information on product availability.
- Streamline warehouse operations by making it easier to track and manage stock allocations across different store locations.

BUSINESS REQUIREMENTS DOCUMENT

Purchase Return JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Purchase Return feature provides a structured way for your company to manage and track the return of goods to suppliers. This system allows you to view a list of all returns, drill down into the specific details of a standard return, and manage the approval process when a supplier confirms the returned items. The feature is designed to handle both standard inventory returns and fixed asset returns, ensuring that all documentation and status tracking remain accurate throughout the lifecycle of the return.

1.2 Step-by-Step Flow

1. Dashboard View: You can view a paginated list of all purchase returns. You can filter this list by status, date range, supplier, or warehouse, and toggle between "Standard" and "Fixed Asset" views.
2. Detailed Inspection: By selecting a specific standard purchase return, you can view its full details, including the items being returned, associated purchase orders, invoices, and the current status of the return.
3. Approval Process: When a return is in the "Sent to Supplier" state, you can access a dedicated approval view. This allows you to review the quantities confirmed by the supplier against the original return request.
4. Validation: The system ensures that you only perform actions appropriate to the current state of the return (e.g., you cannot approve a return that has not yet been sent to the supplier).

1.3 Key Concepts

- Purchase Return: A formal document tracking items sent back to a supplier, including the reason for the return and the quantities involved.
- Workflow State: The current stage of the return process, such as "Draft," "Sent to Supplier," or "Approved." This determines what actions you can take on the record.
- Standard vs. Fixed Asset: A classification of the return type. Standard returns deal with general inventory, while Fixed Asset returns are tracked separately to maintain accurate asset accounting.
- Document Number: A unique reference code (e.g., PR/HO/YYMMNNNN) used to identify and search for specific return records.
- Supplier Confirmation: The process where a supplier verifies the quantity of goods they have received back, which is then recorded in the system to finalize the return.

1.4 Business Value

- Improved Accuracy: By centralizing return data and requiring supplier confirmation, the system reduces discrepancies between your records and the supplier's inventory receipts.
- Operational Efficiency: The ability to filter and sort returns by status or date allows your team to quickly identify pending approvals or overdue returns, streamlining the reconciliation process.

- Audit Readiness: Every return is linked to its original purchase documentation (like purchase orders and invoices), providing a clear, transparent trail for financial and inventory audits.
- Better Decision Making: With clear visibility into return types and reasons, management can identify trends in product quality or supplier performance, helping to reduce future return rates.

BUSINESS REQUIREMENTS DOCUMENT

Purchase Order JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature enables the system to update an existing Purchase Order and its associated line items in a single, reliable operation. It ensures that when a user modifies a purchase order, the header information (such as supplier or delivery details) and the individual line items are updated simultaneously. The system also automatically recalculates the order totals based on the final list of items, ensuring that the financial data always remains accurate and consistent.

1.2 Step-by-Step Flow

1. Header Update: The system updates the main purchase order information (e.g., supplier, warehouse, delivery address, and notes) while verifying that the order belongs to the current company.
2. Item Synchronization: The system compares the submitted list of items with the existing ones:

* Deletions: Any items previously saved but missing from the new submission are removed.

* Updates: Existing items that are included in the submission are updated with the new values (e.g., quantity, price, or discount).

* Additions: Any new items without an existing ID are added to the order.

3. Automatic Recalculation: Once the items are synced, the system calculates the new subtotal, tax, and total amount based on the updated item list.
4. Finalization: The updated purchase order details are saved, and the system returns the refreshed order information. If any part of this process fails, the entire operation is canceled to prevent data errors.

1.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures all changes (header updates, item syncing, and total recalculations) happen together. If one step fails, the entire update is rolled back, leaving the data in its original, valid state.
- Item Synchronization: A smart way of handling list updates where the system intelligently decides whether to delete, update, or create items based on whether they already exist in the database.
- Data Integrity: The process of automatically recalculating financial totals from the line items rather than relying on user-submitted totals, which prevents discrepancies between the order header and its contents.

1.4 Business Value

- Accuracy: By automatically recalculating totals, the system eliminates the risk of human error or "drift" between the individual line items and the final order total.
- Reliability: The use of transactions ensures that a purchase order is never left in a "half-updated" state, providing a consistent and trustworthy record for inventory and accounting.

- Efficiency: Users can manage complex updates to an entire order in one go, knowing the system will handle the underlying data relationships and calculations automatically.

BUSINESS REQUIREMENTS DOCUMENT

Stock Return Warehouse JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature enables the Lumi ERP system to retrieve detailed information about stock returns being sent back to a warehouse. It acts as a bridge between our database and the user interface, ensuring that when a user views a specific stock return, they see a complete and organized summary of the transaction, including the items involved, the current status of the return, and any relevant notes.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view a specific stock return record using its unique identifier.
2. Primary Data Retrieval: The system searches the main stock return records to find the header information, such as the reference code, the store it originated from, the destination warehouse, and the current workflow status (e.g., draft, sent, or approved).
3. Item Retrieval: Once the main record is found, the system automatically looks up all individual products associated with that specific return.
4. Data Consolidation: The system combines the header information and the list of products into a single, structured report.
5. Final Formatting: The system ensures that all information—including optional fields like notes or update timestamps—is presented clearly, even if some of those fields are empty.

1.3 Key Concepts

- Stock Return: A formal process for moving inventory from a store back to a central warehouse or supplier.
- Workflow State: The current stage of the return process, which helps track whether a return is still being prepared (draft) or has been finalized (approved).
- Reference Code: A unique identifier used to track and locate specific return documents within the system.
- Line Items: The individual products included in a return, along with their specific quantities and the reason for the return.

1.4 Business Value

This feature provides a reliable and consistent way to audit inventory movements. By standardizing how stock return data is retrieved and displayed, it reduces errors in inventory tracking and ensures that warehouse staff have accurate, up-to-date information when processing returns. This visibility helps maintain better control over stock levels and improves the efficiency of the supply chain.

BUSINESS REQUIREMENTS DOCUMENT

Company Purchase Return JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature enables the system to record a "Company Purchase Return," which is the process of returning items previously purchased from a supplier. The system captures both the high-level details of the return (such as the supplier, warehouse, and financial totals) and the specific list of items being returned. This ensures that inventory records and financial data remain accurate and synchronized.

1.2 Step-by-Step Flow

1. Initiation: The system receives a request containing the return header information (e.g., supplier, warehouse, total amounts, and workflow status) and a list of individual items to be returned.
2. Header Creation: The system first saves the main return record. This creates a unique identifier for the return, which acts as a reference for the items.
3. Item Registration: Using the unique identifier from the header, the system saves each individual item, including the product details, quantity, price, and the reason for the return.
4. Data Integrity Check: The entire process is handled as a single "all-or-nothing" operation. If any part of the process fails—such as an error saving an item—the system automatically cancels the entire request to prevent incomplete or mismatched data.
5. Confirmation: Once successfully saved, the system returns the complete record of the created purchase return.

1.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures that either the entire return (header and all items) is saved successfully, or nothing is saved at all, preventing data errors.
- Idempotency Token: A unique identifier included in the request that prevents the same return from being accidentally processed or saved twice.
- Header and Line Items: The structure of the data, where the "Header" contains general information about the return, and the "Line Items" contain the specific details for each product involved.
- Workflow State: A status indicator (e.g., "Draft") that tracks the current stage of the return process.

1.4 Business Value

- Data Accuracy: By linking items directly to a specific return header, the system maintains a clear audit trail of what was returned and why.
- Operational Reliability: The "all-or-nothing" approach prevents partial data entries, ensuring that inventory and financial reports are always consistent.
-

Error Prevention: The use of unique request identifiers protects the system from duplicate entries, which is critical for maintaining accurate supplier accounts and inventory levels.

BUSINESS REQUIREMENTS DOCUMENT

Purchase Orders Fixed Asset Table JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides the logic for retrieving and displaying a list of purchase orders within the Lumi ERP system. It is designed to support two distinct views: the "Standard" purchase order list and the "Fixed Assets" purchase order list. By using a unified data retrieval process, the system ensures that users can efficiently filter, sort, and view their procurement records, including real-time counts of related deliveries, invoices, and returns.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a list of purchase orders. It automatically identifies the user's company to ensure data privacy and security.
2. Filtering: The system applies any user-selected filters, such as the order type, specific date ranges, supplier information, or the "Fixed Asset" status (which determines whether the order appears on the Standard or Fixed Assets tab).
3. Data Retrieval: The system fetches the core purchase order details from the database.
4. Information Enrichment: For every order found, the system automatically looks up the associated supplier and warehouse names to provide a human-readable display.
5. Document Counting: The system performs a real-time calculation to count how many delivery documents, invoices, and return documents are linked to each purchase order.
6. Pagination and Sorting: The final list is sorted according to user preferences (e.g., by date or reference code) and paginated to ensure the interface remains fast and responsive.
7. Response: The system returns the organized list of orders along with the total count of records to support the pagination controls in the user interface.

1.3 Key Concepts

- Fixed Asset Flag: A simple true/false indicator that categorizes a purchase order, allowing the system to separate standard procurement from fixed asset acquisitions.
- Dynamic Counting: Instead of storing static numbers, the system calculates the number of related documents (deliveries, invoices, returns) on the fly, ensuring the information is always up-to-date.
- Scope: All data is automatically filtered by the user's company, preventing cross-company data visibility.
- Pagination: A method of breaking large lists into smaller, manageable pages (e.g., 20 items at a time) to improve system performance.
- Workflow State: The current status of an order (e.g., Draft, Sent, Received, or Cancelled), which helps users track the progress of their procurement.

1.4 Business Value

- Improved Organization: By separating standard purchases from fixed assets, procurement teams can manage their workflows more effectively without cluttering their view.
- Operational Visibility: Users can see at a glance how many invoices or deliveries are associated with a specific order, reducing the need to click into individual records to check their status.
- Performance and Scalability: The use of efficient database queries and pagination ensures that the system remains fast, even as the company's volume of purchase orders grows over time.
- Data Accuracy: Because the system calculates related document counts dynamically, users are guaranteed to see the most current status of their orders without manual reconciliation.

BUSINESS REQUIREMENTS DOCUMENT

Stock Outgoing JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Stock Outgoing" feature allows the system to track inventory items leaving a store or warehouse for reasons other than a direct sale. This process ensures that stock levels are accurately reduced and that the financial impact is recorded in the company's accounting journals. The feature manages the entire lifecycle of these movements, from initial draft creation to final approval.

1.2 Step-by-Step Flow

1. Creation: A user creates a "Stock Outgoing" document in a "Draft" state. The system validates that the requested items are available at the selected source location.
2. Drafting & Editing: Users can update, add, or remove items from the draft as needed.
3. Confirmation: Once the details are finalized, the document is moved to a "Confirmed" state. The system performs a final check to ensure the stock is still available.
4. Approval: Upon approval, the system performs several critical actions:

* It locks the document to prevent further changes.

* It calculates the final costs for the items.

* It permanently reduces the inventory levels at the source.

* It generates a formal journal entry to reflect the financial movement.

* The document status is updated to "Approved."

5. Listing & Viewing: Users can search, filter, and view a list of all stock outgoing records, or drill down into the details of a specific document to see its history, linked work orders, and financial impact.

1.3 Key Concepts

- Stock Outgoing: A record representing inventory leaving a specific location (store or warehouse) without an associated customer sale.
- Workflow State: The status of a document, which dictates what actions can be taken (e.g., "Draft" can be edited, "Approved" is final).
- Source: The specific location (store or warehouse) from which the inventory is being removed.
- Journal Entry: An accounting record created automatically upon approval to ensure the inventory reduction is reflected in the company's financial books.
- Line Items: The individual products included in a single stock outgoing document, each with its own quantity and cost details.

1.4 Business Value

- Inventory Accuracy: By requiring a formal approval process and real-time stock checks, the system prevents inventory discrepancies and ensures that stock levels always reflect reality.
- Financial Integrity: The automatic generation of journal entries ensures that every movement of goods is accounted for financially, reducing manual bookkeeping errors.
- Operational Visibility: The ability to list, filter, and track these movements provides management with clear insights into where inventory is going and why, supporting better decision-making and auditing.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Order Create JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Franchise Purchase Order Create" feature allows the system to process and record new purchase orders for franchises. This feature ensures that all order details—such as the source warehouse, destination store, supplier, and specific product quantities—are thoroughly validated before being saved. By using a structured, automated process, the system ensures data integrity and prevents errors like duplicate items or invalid product requests.

1.2 Step-by-Step Flow

1. Validation: The system checks the incoming request to ensure the order type (internal or external) is valid and that all referenced entities (Supplier, Warehouse, Store, and Products) exist, are active, and belong to the correct company. It also verifies that product quantities are positive and that no duplicate products are included.
2. Header Creation: Once validated, the system creates the main "Stock Order" record, which acts as the header for the order. This includes generating a unique reference code and setting the initial status to "draft."
3. Item Processing: The system adds the individual products to the order. During this step, it captures "snapshots" of current data, such as the warehouse's average cost and the product's supply price, ensuring these values remain accurate to the time of the order.
4. Total Calculation: The system automatically calculates the total order amount based on the items added.
5. Workflow Initialization: An initial record is created in the workflow history to track the order's lifecycle, starting it in the "draft" state.
6. Confirmation: The system returns the fully created order details to the user, confirming that the entire process was successful.

1.3 Key Concepts

- Transaction: A safety mechanism that ensures all steps of the order creation succeed together. If any part of the process fails (e.g., a product is invalid), the entire operation is canceled to prevent incomplete or corrupt data.
- Idempotency Token: A unique identifier (request ID) used to ensure that the same order is not accidentally created twice if a request is sent multiple times.
- Snapshot: A record of data (like product prices or stock levels) taken at the exact moment the order is created, which remains unchanged even if those values are updated in the system later.
- Workflow State: The current status of the order (e.g., "draft"), which helps manage the order's progress through the system.

1.4 Business Value

- Data Accuracy: By validating all inputs against existing records (Suppliers, Warehouses, Stores) before saving, the system prevents common data entry errors.
- Operational Efficiency: Automating the calculation of order totals and the creation of workflow history reduces manual work and ensures consistency across all franchise orders.
- Auditability: Every order is linked to a specific user and company, and the workflow history provides a clear, append-only record of the order's status, which is essential for tracking and reporting.
- Reliability: The use of transaction-based processing ensures that the system never ends up in a "half-finished" state, providing peace of mind that every order is either fully recorded or not recorded at all.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Order Response Shape

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature establishes a standardized way for the Lumi ERP system to retrieve and display information about Franchise Purchase Orders. By defining a consistent "response shape," we ensure that whenever the system looks up a purchase order, it provides a predictable set of details—such as the order status, the locations involved, and relevant dates—in a format that other parts of the application can easily understand and use.

1.2 Step-by-Step Flow

1. Request: The system receives a request to look up a specific Franchise Purchase Order using its unique identification code.
2. Data Retrieval: The system searches the database for the record matching that specific ID.
3. Validation: The system confirms that the record exists. If no record is found, it triggers an error notification to prevent the system from processing empty or invalid data.
4. Formatting: Once the record is located, the system maps the raw database information into the standardized "Response Shape," ensuring all required fields (like the order ID, reference code, current status, and source/destination locations) are present.
5. Delivery: The formatted information is returned to the user or the requesting system component.

1.3 Key Concepts

- Response Shape: A predefined template that dictates exactly what information is included when we fetch a purchase order, ensuring consistency across the entire platform.
- Workflow State: A tracking mechanism that identifies the current stage of the order (e.g., whether it is a draft, confirmed by the store, sent by the warehouse, or received by the store).
- Reference Code: A unique identifier used to track and label the purchase order for easy searching and communication.
- Unique Identifier (UUID): A permanent, system-generated ID that ensures every purchase order is distinct and cannot be confused with another.

1.4 Business Value

- Operational Consistency: By standardizing the data format, we reduce the risk of errors when different parts of the ERP system communicate with each other.
- Improved Reliability: The clear definition of required fields ensures that critical information—such as where an order is coming from and where it is going—is never missing.
-

Easier Troubleshooting: Because the system explicitly checks for the existence of an order and provides a clear error if it is missing, support teams can quickly identify and resolve issues when a record cannot be found.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Return JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Franchise Purchase Return feature allows stores to formally return items to a supplier based on a previous purchase order. This process ensures that returns are tracked accurately, preventing stores from returning more items than they originally received or more than they currently have in stock. The system automatically handles the creation of the return document and validates all quantities against real-time inventory data to maintain accuracy.

1.2 Step-by-Step Flow

1. Validation: The system checks the request to ensure the return is valid. It verifies that the purchase order exists, belongs to the correct company, and matches the store and supplier involved.
2. Quantity Verification: The system calculates the maximum returnable quantity for each item by looking at the original order and subtracting any items already returned. It also confirms the store currently has enough stock on hand to fulfill the return.
3. Header Creation: Once validated, the system creates a "Draft" return document. It automatically generates a unique reference code for the document; this cannot be manually overridden by the user.
4. Item Processing: The system records each item being returned, linking it to the original purchase order line. It automatically pulls in necessary details like the original supply price and current stock levels.
5. Finalization: The system returns the complete, newly created document to the user. If any part of this process fails (e.g., a validation error), the entire operation is cancelled to ensure no partial or incorrect data is saved.

1.3 Key Concepts

- Source Order: The original purchase order that serves as the basis for the return. The system uses this to track what was originally received.
- Return Cap: A calculated limit that prevents a store from returning more items than were originally received on a specific order line.
- Draft State: The initial status of a new return, indicating it has been created but not yet processed or approved.
- Transaction: A safety mechanism that ensures all steps of the return (validation, header creation, and item recording) happen together. If one step fails, the entire return is discarded to prevent data errors.
- Snapshot Data: Information (such as prices or quantities) captured at the exact moment the return is created, ensuring the record remains accurate even if inventory levels change later.

1.4 Business Value

- Prevents Over-Returning: By automatically calculating return caps, the system eliminates the risk of human error or fraud regarding return quantities.
-

Data Integrity: Because the system generates document numbers and pulls pricing/stock data directly from the database, it ensures that return records are consistent and reliable for accounting and inventory audits.

- Operational Efficiency: The automated validation process reduces the need for manual checks, allowing staff to process returns quickly while maintaining strict adherence to business rules.

BUSINESS REQUIREMENTS DOCUMENT

Franchise Purchase Order Status Transition JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature manages the lifecycle of Franchise Purchase Orders within the Lumi ERP system. It ensures that when a store receives an order, the system accurately updates the store's inventory levels and maintains a clear audit trail. The process is designed to be "atomic," meaning that all related updates—such as changing the order status, adjusting stock counts, and logging history—happen together as a single, reliable action. If any part of the process fails, the entire operation is canceled to prevent data errors.

1.2 Step-by-Step Flow

1. Verification and Locking: When a "receive order" request is initiated, the system first locks the specific purchase order to ensure no other changes can be made to it simultaneously. It verifies that the order is currently in the "placed" state.
2. Processing Line Items: For every product in the order, the system:

* Updates the specific item record with the received quantity and cost.
* Checks the store's current stock levels.
* Either increases the existing stock count or creates a new stock record if the product is new to that store.
* Records a detailed history entry to track the inventory movement.

3. Finalizing the Order: Once all items are processed, the system updates the order status to "store_received," adds a unique reference code, and saves the final notes.
4. Completion: The transaction is finalized. If any step fails (e.g., the order was already processed), the system rolls back all changes to ensure the inventory remains accurate.

1.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures a group of database changes either all succeed together or all fail together, preventing partial or corrupted data.
- Locking (SELECT ... FOR UPDATE): A method of "reserving" a record so that no other user or process can modify it until the current operation is finished, preventing conflicts.
- Inventory Reconciliation: The process of automatically updating store stock levels based on received purchase orders, ensuring the digital inventory matches physical reality.
- Audit Trail: A history log that tracks every inventory change, providing accountability and visibility into why and when stock levels were adjusted.

1.4 Business Value

-

Data Integrity: By using atomic transactions and locking, the system prevents common errors like double-counting inventory or processing the same order twice.

- Operational Efficiency: Automating the transition from "placed" to "received" reduces manual data entry and minimizes the risk of human error during the receiving process.
- Accurate Reporting: Because inventory and history logs are updated in real-time as part of the receiving flow, store managers have immediate access to accurate stock levels and reliable audit records for financial and operational oversight.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/supplier

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for users to retrieve a complete list of suppliers associated with their specific company. By using this tool, authorized users can view essential supplier details—such as names and contact information—directly within the Lumi ERP system. The system automatically ensures that users only see suppliers relevant to their own organization, maintaining data privacy and security.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies the user's identity. If the user is not logged in or their session is invalid, the request is denied.
2. Data Retrieval: Once verified, the system identifies the user's company and automatically fetches all associated suppliers from the database.
3. Display: The system presents the list of suppliers, organized alphabetically by name, to the user. If no suppliers are found or a system error occurs, the user receives a clear notification regarding the status of their request.

1.3 Key Concepts

- Authentication: A security step that confirms who is making the request to ensure only authorized personnel can access company data.
- Data Scoping: A privacy feature that automatically filters information so that users only see data belonging to their own company, preventing access to other organizations' records.
- Alphabetical Sorting: The list is automatically arranged from A to Z by supplier name to ensure the information is easy to read and navigate.

1.4 Business Value

- Efficiency: Provides instant access to supplier contact information without requiring manual searches or external reports.
- Security: Ensures that sensitive supplier data is protected by strictly limiting access to authenticated users and restricting visibility to their own company’s records.
- Consistency: By standardizing how supplier information is retrieved and displayed, the system ensures that all team members are working with the same accurate, up-to-date information.

2. Data

2.1 Overview

This feature provides a secure way for authorized users to retrieve a list of suppliers associated with their company. The system automatically identifies which company the user belongs to, ensuring they only see relevant supplier data, which is presented in alphabetical order by name.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to access the data. If the user is not authenticated, the request is rejected.
2. Company Identification: The system identifies the user's company automatically based on their account credentials.
3. Data Retrieval: The system searches the database for all suppliers linked to that specific company.
4. Sorting: The retrieved list is organized alphabetically by the supplier's name.
5. Delivery: The final list is returned to the user. If the list cannot be found or an unexpected system error occurs, the user receives an appropriate error notification.

2.3 Key Concepts

- Authentication: The process of verifying the user's identity to ensure they have permission to view company-specific information.
- Data Scoping: A security measure that automatically filters information so that users only see data belonging to their own organization, preventing unauthorized access to other companies' records.
- Alphabetical Ordering: A standard display format where the supplier list is automatically sorted from A to Z by name for easier navigation.

2.4 Business Value

- Security and Privacy: By automatically scoping data to the user's company, we ensure that sensitive supplier information remains private and is only accessible to the correct personnel.
- Efficiency: Users do not need to manually search or filter for their company's suppliers; the system handles this automatically, providing a clean, ready-to-use list.
- Consistency: Standardizing the list order (alphabetical) ensures a predictable and professional user experience across the platform.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/suppliers?{filters}&{pagination}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of suppliers associated with your company. It is designed to be flexible, allowing you to search for specific suppliers by name, status, or tax ID, while also managing large lists through pagination. The system automatically ensures that users only see suppliers belonging to their own organization, maintaining data security and relevance.

1.2 Step-by-Step Flow

1. Authentication: The system identifies your company based on your login credentials to ensure you only access your own supplier data.
2. Parameter Processing: The system checks your request for any specific filters (such as a supplier name or status) and pagination settings (how many results to show and where to start).
3. Data Filtering: The system searches the database, applying your requested filters to narrow down the list of suppliers.
4. Sorting and Formatting: The system automatically organizes the resulting list alphabetically by supplier name.
5. Delivery: The system returns the final, paginated list of suppliers to you. If any errors occur during this process, the system provides a clear status code to explain the issue.

1.3 Key Concepts

- Filters: Specific criteria used to narrow down search results, such as searching by a supplier's name, their current status, or their tax identification number.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks. You can control the "limit" (how many items appear on a page) and the "offset" (how many items to skip before starting the list).
- Scoped Access: A security measure that automatically restricts the data returned to only those records associated with your specific company, preventing unauthorized access to other organizations' data.
- Default Ordering: To ensure consistency, the system always presents the supplier list in alphabetical order by name, regardless of the filters applied.

1.4 Business Value

This feature improves operational efficiency by allowing users to quickly locate specific suppliers without manually scanning through long lists. By providing built-in filtering and pagination, the system remains fast and responsive even as your supplier database grows. Furthermore, the automated scoping ensures that sensitive supplier information remains secure and isolated to the correct company account.

2. Data

2.1 Overview

This feature provides a secure and efficient way for users to retrieve a list of their company's suppliers. By using this endpoint, users can search for specific suppliers based on criteria like name, status, or tax ID, while also managing large lists through pagination. The system automatically ensures that users only see data belonging to their own organization, maintaining strict data privacy.

2.2 Step-by-Step Flow

1. Authentication Check: The system identifies the user's company to ensure all subsequent data retrieval is restricted to that specific organization.
2. Filter Application: The system checks the request for optional search criteria. If provided, it narrows the results by supplier name, status, or tax ID.
3. Sorting: The system automatically organizes the resulting list alphabetically by the supplier's name.
4. Pagination: The system applies limits and offsets to the results, ensuring that only a manageable "page" of data is returned at one time.
5. Data Delivery: The system returns the final, filtered, and paginated list to the user. If the request is invalid or an error occurs, the system provides a clear status code to explain the issue.

2.3 Key Concepts

- Filtering: The ability to narrow down a large list of suppliers by specific attributes (e.g., finding all "Active" suppliers).
- Pagination: A method of breaking a large dataset into smaller, manageable chunks to improve performance and readability.
- Data Scoping: A security measure that automatically limits the search results to only those suppliers associated with the user's company, preventing unauthorized access to other companies' data.
- Alphabetical Ordering: A consistent display format where results are always sorted by name, ensuring a predictable user experience.

2.4 Business Value

This feature improves operational efficiency by allowing staff to quickly locate specific supplier information without manually scanning through entire databases. By implementing built-in pagination and filtering, the system remains fast and responsive even as the number of suppliers grows. Furthermore, the automatic scoping ensures that sensitive supplier data remains secure and compliant with internal privacy standards.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/suppiler

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way to add new suppliers to the Lumi ERP system. It ensures that only authorized users can create supplier records and includes built-in safeguards to prevent duplicate entries by verifying the supplier's tax identification number before saving.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to create a new supplier.
2. Data Validation: The system checks that all mandatory information—specifically the supplier's name, tax ID, and email address—is provided.
3. Duplicate Check: The system searches the database using the provided tax ID to ensure a supplier with that identity does not already exist.
4. Record Creation: If the data is valid and no duplicate is found, the system creates the new supplier record, assigns it a unique identifier, and records the creation date.
5. Confirmation: The system returns a success message along with the newly created supplier details. If any step fails (such as missing data or a duplicate tax ID), the system provides an appropriate error message.

1.3 Key Concepts

- Authentication: The process of confirming the user's identity to ensure they are allowed to access the system.
- Authorization: The process of verifying that the authenticated user has the specific "create" permission required for this task.
- Validation: A quality control step that ensures all required information is present before the system attempts to save the data.
- Conflict Check: A safety mechanism that prevents the system from creating duplicate records for the same entity by checking unique identifiers like a tax ID.

1.4 Business Value

- Data Integrity: By automatically checking for existing tax IDs, the system prevents duplicate supplier records, keeping your vendor database clean and accurate.
- Security: Strict access controls ensure that only authorized personnel can modify supplier information, protecting sensitive business data.
-

Operational Efficiency: Standardizing the supplier creation process reduces manual errors and ensures that all necessary contact and tax information is captured consistently from the start.

2. Data

2.1 Overview

The "Create Supplier" feature provides a secure and standardized way to add new suppliers to the Lumi ERP system. This API endpoint ensures that all supplier data is validated before being saved, preventing duplicate entries and ensuring that essential contact and identification information is captured correctly.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user has the necessary permissions and valid credentials to add a new supplier.
2. Duplicate Prevention: The system checks the provided Tax ID against existing records. If a supplier with that Tax ID already exists, the request is rejected to maintain data integrity.
3. Data Validation: The system confirms that all mandatory fields—specifically the supplier's name, Tax ID, and email address—are provided. If any are missing, the request is rejected.
4. Record Creation: Once all checks pass, the system generates a unique identifier for the supplier, records the current date and time, and saves the information into the database.
5. Confirmation: Upon successful storage, the system confirms the creation of the new supplier record.

2.3 Key Concepts

- Tax ID: A unique identifier used to distinguish one supplier from another and prevent duplicate entries in the system.
- Validation: The process of ensuring that the information submitted is complete and accurate before it is permanently saved.
- Data Integrity: The practice of maintaining consistent and accurate data by preventing errors, such as duplicate supplier profiles.
- API Endpoint: A digital gateway that allows external systems or applications to communicate with the Lumi ERP to perform specific tasks, such as creating a supplier.

2.4 Business Value

- Data Accuracy: By enforcing mandatory fields and checking for duplicates, the system prevents "dirty data" and ensures that every supplier profile is complete and unique.
-

Operational Efficiency: Automating the supplier creation process reduces manual data entry errors and allows for faster onboarding of new business partners.

- Security: By requiring authentication and permissions, the system ensures that only authorized personnel can modify the supplier database, protecting sensitive business information.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/supplier/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way to retrieve detailed information about a specific supplier within the Lumi ERP system. When a user requests a supplier's profile, the system verifies the user's identity and ensures they only have access to supplier records associated with their own company. This ensures data privacy and prevents unauthorized access to sensitive supplier information.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a specific supplier using a unique identifier.
2. Input Validation: The system checks that the provided identifier is in the correct format. If the format is incorrect, the request is rejected.
3. Security & Ownership Check: The system searches for the supplier record, ensuring that the record exists and specifically belongs to the company of the user currently logged in.
4. Data Retrieval: If the supplier is found and the ownership check passes, the system gathers all relevant details, such as contact information, credit limits, and payment terms.
5. Response: The system returns the full supplier profile to the user. If the supplier cannot be found or if the user does not have permission to view it, an error message is provided.

1.3 Key Concepts

- Unique Identifier: A specific code used to pinpoint an exact supplier record in the database.
- Data Isolation: A security practice that ensures users can only view information relevant to their own organization, preventing cross-company data leaks.
- Authentication: The process of verifying who the user is before allowing them to access or view any supplier data.
- Validation: A preliminary check to ensure the request is formatted correctly before the system attempts to process it.

1.4 Business Value

- Data Security: By enforcing company-level ownership checks, the system guarantees that sensitive supplier data remains confidential and accessible only to authorized personnel.
- Operational Efficiency: Centralizing supplier details—including credit terms, contact info, and notes—into a single, reliable source allows teams to manage supplier relationships more effectively.
-

System Reliability: Standardized error handling ensures that users receive clear feedback if a request fails, helping to maintain a smooth and predictable user experience.

2. Data

2.1 Overview

This feature allows the system to retrieve detailed information about a specific supplier. When a user requests a supplier's profile, the system ensures that the request is valid and that the user has the appropriate permissions to view that specific supplier's data. This ensures that sensitive supplier information remains secure and is only accessible to the company that owns the record.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view a specific supplier, identified by a unique ID.
2. Format Validation: The system checks that the provided ID is in the correct format. If the format is incorrect, the request is rejected.
3. Data Retrieval & Authorization: The system searches the database for the supplier record. Crucially, it filters this search to ensure the supplier belongs to the same company as the user making the request.
4. Verification:

– If the supplier is found and belongs to the user's company, the full supplier details are returned.

– If the supplier does not exist, or if it belongs to a different company, the system reports that the record could not be found.

2.3 Key Concepts

– Unique Identifier (ID): A specific, permanent code used to distinguish one supplier from another within the system.

– Data Scoping: A security measure that restricts a user's access so they can only view records associated with their own company.

– Validation: The process of checking that incoming information (like an ID) is formatted correctly before the system attempts to process it.

– Authorization: The process of verifying that the person requesting the data has the right to see it.

2.4 Business Value

This feature provides a reliable and secure way for team members to access comprehensive supplier profiles, including contact details, credit limits, and payment terms. By enforcing strict data scoping, the system protects

business intelligence by ensuring that supplier relationships and terms remain private to the specific company managing them, preventing unauthorized access across different organizational accounts.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/supplier/:id/status

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a simple way to toggle a supplier's status between "active" and "inactive" within the Lumi ERP system. By using this update tool, you can quickly manage your supplier list, ensuring that only currently relevant partners are marked as active in your records.

1.2 Step-by-Step Flow

1. Request Submission: You provide the unique ID of the supplier you wish to update and specify the new status (active or inactive).
2. Validation: The system checks that the request is formatted correctly and that the status provided is a valid "on/off" choice.
3. Verification: The system searches for the supplier. It confirms the supplier exists and ensures that the supplier belongs to your company, preventing unauthorized access to other companies' data.
4. Update: If everything is correct, the system updates the supplier's status and records the exact time the change was made.
5. Confirmation: The system returns a success message containing the supplier's ID, their new status, and the timestamp of the update. If any errors occur (such as an invalid request or a missing supplier), the system will provide an appropriate error message.

1.3 Key Concepts

- Supplier Status: A simple toggle (active/inactive) that determines if a supplier is currently available for business operations.
- Ownership Verification: A security measure that ensures you can only modify suppliers associated with your specific company account.
- Timestamping: An automatic record of when the status was last changed, providing an audit trail for your supplier management.

1.4 Business Value

This feature streamlines supplier management by allowing for real-time updates to your vendor database. It reduces manual administrative work and helps maintain data integrity by ensuring that your active supplier list is always up-to-date, which is critical for accurate procurement and reporting.

2. Data

2.1 Overview

This feature provides a secure way to update the status of a supplier (e.g., marking them as "active" or "inactive") within the Lumi ERP system. It allows authorized users to toggle a supplier's availability, ensuring that only companies with the correct permissions can modify their own supplier records.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to update a specific supplier's status, identifying the supplier by their unique ID and providing the new status (active or inactive).
2. Security & Ownership Check: The system attempts to update the record, but it strictly limits this action to suppliers that belong to the company currently making the request.
3. Validation:

* If the update is successful, the system confirms the change and provides the updated status and timestamp.

* If the update fails, the system checks if the supplier exists at all. If the supplier does not exist, it reports that the record could not be found. If the supplier exists but belongs to a different company, the system denies the request to protect data privacy.

2.3 Key Concepts

- Data Isolation: A security measure that ensures a company can only view or modify its own supplier data, preventing unauthorized access to other companies' information.
- Status Toggle: The ability to switch a supplier between "active" and "inactive" states, which helps manage procurement workflows and supplier relationships.
- Authentication Context: The system automatically recognizes which company is making the request, ensuring that the "ownership" check happens seamlessly in the background.

2.4 Business Value

This feature improves operational control and data security. By allowing businesses to easily deactivate suppliers, companies can maintain accurate records and prevent accidental transactions with inactive partners. Furthermore, the built-in ownership checks ensure that sensitive supplier information remains private and protected from unauthorized access by other organizations using the platform.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/supplier/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to update the details of an existing supplier within the Lumi ERP system. It provides a secure way to modify contact information—such as the supplier's name, email, phone number, or internal supplier code—while ensuring that sensitive system-generated data remains protected and that updates are restricted to the user's own company records.

1.2 Step-by-Step Flow

1. Identification: The system identifies the specific supplier to be updated using a unique ID provided in the request.
2. Authentication Check: The system verifies that the user is logged in and confirms that the supplier record belongs to their specific company.
3. Validation: The system checks the incoming data to ensure only allowed fields (like name or contact details) are being changed. If a user attempts to modify protected fields (such as the creation date or company ID), the request is rejected.
4. Conflict Check: If the user is updating the "supplier code," the system verifies that the new code is not already in use by another supplier within the same company.
5. Update: Once all checks pass, the system saves the changes to the database and returns the updated supplier profile.

1.3 Key Concepts

- Editable Fields: Specific pieces of information, such as contact details and supplier codes, that a user is permitted to change.
- System-Managed Fields: Critical data points (like creation timestamps or internal IDs) that are automatically handled by the software and cannot be altered by users.
- Ownership Validation: A security measure that ensures users can only view or modify suppliers associated with their own company.
- Conflict Resolution: A safeguard that prevents duplicate supplier codes, ensuring each supplier remains uniquely identifiable within the company's records.

1.4 Business Value

This feature streamlines supplier management by allowing for quick, self-service updates to contact information. By enforcing strict validation and ownership rules, it maintains data integrity and prevents accidental or unauthorized

changes to critical system records. Additionally, the conflict check prevents operational errors that could arise from duplicate supplier identification codes.

2. Data

2.1 Overview

This feature allows users to update existing supplier information within the Lumi ERP system. It provides a secure way to modify contact details or other editable fields for a specific supplier while ensuring that data integrity is maintained and that users only modify records belonging to their own company.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to perform the update.
2. Supplier Identification: The system locates the specific supplier record using the unique ID provided in the request.
3. Ownership Verification: The system confirms that the supplier record belongs to the same company as the user making the request. If the supplier cannot be found or belongs to a different company, the request is rejected.
4. Data Validation: The system checks the incoming update information. It ensures that any new "supplier code" provided is not already being used by another supplier within the same company.
5. Record Update: If all checks pass, the system updates the supplier's information with the new details provided.
6. Confirmation: The system returns a success message confirming the update is complete.

2.3 Key Concepts

- Supplier: A business entity or partner stored in the system that provides goods or services.
- Unique Identifier (ID): A specific, permanent reference code used to ensure the system is updating the correct supplier record.
- Supplier Code: A unique reference label for a supplier within a company; the system prevents two different suppliers from sharing the same code.
- Data Integrity: The process of ensuring that updates are valid, authorized, and do not create conflicts (like duplicate codes) within the database.

2.4 Business Value

- Data Accuracy: Allows teams to keep supplier contact information and records up-to-date without needing to delete and recreate entries.
-

Security and Privacy: Prevents unauthorized access by ensuring users can only view or modify suppliers associated with their specific company.

- Conflict Prevention: Automatically prevents errors by checking for duplicate supplier codes, ensuring that the company's internal filing system remains organized and reliable.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/v1/suppliers/:id/products?{field}={value}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to search and retrieve a list of products associated with a specific supplier. It allows users to narrow down results using specific criteria—such as product name, SKU, or discount percentage—while also supporting pagination to ensure the system remains fast and easy to navigate when dealing with large product catalogs.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is authorized to access the data. If not, the request is rejected.
2. Supplier Verification: The system checks if the requested supplier exists in the database. If the supplier cannot be found, an error is returned.
3. Filter Validation: The system reviews any search criteria provided (like SKU or name). If an unsupported filter is used, the system alerts the user that the request is invalid.
4. Pagination Setup: The system determines which "page" of results to show and how many items should appear on that page (defaulting to 25 items if not specified).
5. Data Retrieval: The system searches the database for products matching the supplier and the applied filters, then returns the list of products to the user.

1.3 Key Concepts

- Supplier ID: A unique identifier used to ensure we are looking at the correct supplier's catalog.
- Filters: Specific criteria (SKU, product name, or discount percentage) that allow users to find exact products rather than browsing the entire list.
- Pagination: A method of breaking a large list of products into smaller, manageable chunks (pages) to improve performance and readability.
- Authentication: A security gate that ensures only verified users can access supplier product information.

1.4 Business Value

This feature empowers users to quickly locate specific items within a supplier's inventory without having to manually sort through thousands of records. By providing flexible search and pagination, the system improves operational efficiency for procurement and inventory management teams, ensuring they can find the right product data exactly when they need it.

2. Data

2.1 Overview

This feature provides a way to search and retrieve a list of products associated with a specific supplier. It allows users to narrow down results using specific criteria—such as product name, SKU, or discount percentage—and includes pagination to ensure the system remains fast and responsive even when a supplier has a large catalog of products.

2.2 Step-by-Step Flow

1. Supplier Verification: The system first checks if the requested supplier exists in the database. If the supplier cannot be found, the request is rejected.
2. Base Query Setup: Once the supplier is confirmed, the system prepares to pull all products linked to that specific supplier ID.
3. Applying Filters: The system checks for any search criteria provided by the user (SKU, product name, or discount percentage) and applies them to the search to narrow down the results.
4. Pagination: The system calculates which "page" of results to show based on the user's request, ensuring only a manageable number of items are returned at once.
5. Data Retrieval: The system executes the final search and returns the filtered, paginated list of products to the user.

2.3 Key Concepts

- Supplier ID: A unique identifier used to ensure we are only looking at products belonging to the correct supplier.
- Dynamic Filtering: The ability to search by specific attributes (like SKU or name) only when the user provides them, making the search flexible.
- Pagination: A method of breaking a large list of items into smaller, manageable chunks (pages) to improve performance and readability.
- Case-Insensitive Search: When searching by name or SKU, the system will find matches regardless of whether the user typed in uppercase or lowercase letters.

2.4 Business Value

This feature improves the efficiency of the Lumi ERP platform by allowing users to quickly locate specific items within a supplier's catalog. By supporting targeted searches and pagination, it reduces the time spent manually browsing through long lists of products, leading to a smoother and more productive workflow for procurement and inventory management teams.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/supplier/:id/products

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way to retrieve a list of products associated with a specific supplier within the Lumi ERP system. By using this tool, authorized users can quickly pull product details—such as names, stock-keeping units (SKUs), and pricing—for any supplier linked to their company. The system includes built-in safeguards to ensure that users can only access data for suppliers they are authorized to view.

1.2 Step-by-Step Flow

1. Validation: The system checks that the provided supplier identifier is formatted correctly.
2. Authentication: The system verifies that the person making the request is logged in and authorized to use the platform.
3. Access Control: The system confirms that the requested supplier exists and belongs to the user's company. If the supplier cannot be found or belongs to a different organization, access is denied.
4. Data Retrieval: The system fetches the list of products for that supplier. To keep performance fast, the results are provided in manageable chunks (pages).
5. Delivery: The system returns the product information, including the product ID, name, SKU, and price, to the user.

1.3 Key Concepts

- Supplier Identifier: A unique code used to pinpoint a specific supplier in the database.
- Authentication: The security process that confirms the identity of the user making the request.
- Access Control: A security measure that ensures users can only view data belonging to their own company, preventing unauthorized access to other organizations' information.
- Pagination: A method of breaking large lists of data into smaller, easier-to-handle pages to ensure the system remains responsive.
- SKU (Stock-Keeping Unit): A unique code used to track individual products in inventory.

1.4 Business Value

This feature streamlines inventory management by allowing users to programmatically access supplier product catalogs. It reduces manual data entry and ensures that internal systems are always synchronized with the most current product information, pricing, and SKUs. Furthermore, the built-in security checks ensure that sensitive supplier data remains protected and accessible only to the appropriate company personnel.

2. Data

2.1 Overview

This feature provides a secure way to retrieve a list of products associated with a specific supplier within the Lumi ERP system. It is designed to ensure that users can only access product information for suppliers that are officially linked to their own company, maintaining strict data privacy and security.

2.2 Step-by-Step Flow

1. Verification: The system first checks if the requested supplier exists and confirms that it is associated with the user's company. If the supplier cannot be found or does not belong to the company, the request is denied.
2. Pagination Calculation: The system calculates which "page" of results to show based on the user's request, ensuring that large lists of products are broken down into manageable chunks.
3. Data Retrieval: The system fetches the specific batch of products for that supplier, sorted alphabetically by name.
4. Metadata Compilation: The system counts the total number of products available for that supplier to help the user understand the full scope of the list.
5. Response: The system returns the requested list of products along with summary information, such as the current page number and the total count of items.

2.3 Key Concepts

- Authentication/Authorization: A security check that ensures the user has permission to view data belonging to their specific company.
- Pagination: A method of splitting a large list of items into smaller, easier-to-read pages to improve system performance and user experience.
- Supplier-Product Association: The logical link in the database that ensures a product is correctly attributed to the supplier that provides it.
- Metadata: Additional information provided with the product list, such as the total number of items, which helps the user navigate through the data.

2.4 Business Value

This feature enables procurement and inventory teams to efficiently browse supplier catalogs directly within the ERP. By enforcing company-level security, it prevents unauthorized access to sensitive supplier data. Furthermore, the use of pagination ensures that the system remains fast and responsive, even when dealing with suppliers that offer thousands of individual products.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/suppliers/:id/history

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a secure way to view the audit trail for any specific supplier within the Lumi ERP system. By accessing this history, users can see a chronological record of all changes made to a supplier's profile, including who made the change, when it occurred, and what specific information was updated. To ensure data security, the system verifies that the user is authorized to view the requested supplier before displaying any information.

1.2 Step-by-Step Flow

1. Request Initiation: The user requests the history for a specific supplier by providing the supplier's unique ID.
2. Security Verification: The system checks if the supplier exists and confirms that it belongs to the user's company. If the supplier cannot be found or belongs to a different company, the request is denied.
3. Data Retrieval: The system fetches the change history for that supplier.
4. Sorting and Formatting: The history records are organized starting with the most recent changes first.
5. Pagination: The system applies pagination (based on the requested page and limit) to ensure the data is returned in manageable chunks.
6. Delivery: The requested list of changes is returned to the user.

1.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific supplier record.
- Pagination: A method of dividing a large list of records into smaller, discrete pages to improve performance and readability.
- Authentication: The process of verifying the identity of the user to ensure they only access data belonging to their own company.
- UUID: A unique identifier assigned to each supplier to ensure the system retrieves the correct record without ambiguity.

1.4 Business Value

This feature enhances transparency and accountability within the supply chain management process. By maintaining a clear history of changes, businesses can easily track modifications, troubleshoot data discrepancies, and maintain compliance by knowing exactly when and by whom supplier information was altered. The built-in security checks ensure that sensitive supplier data remains protected and accessible only to authorized personnel within the correct organization.

2. Data

2.1 Overview

This feature provides a way to view the audit trail for a specific supplier. By requesting the history for a supplier, users can see a chronological log of changes made to that supplier's information. To ensure data security, the system verifies that the user is authorized to view the requested supplier before returning any information.

2.2 Step-by-Step Flow

1. Verification: The system checks if the requested supplier exists and confirms that it belongs to the company associated with the user making the request. If the supplier cannot be found or the user does not have permission to view it, the request is denied.
2. Pagination Setup: The system calculates which specific "slice" of the history records to retrieve based on the page number and the number of items requested per page.
3. Data Retrieval: The system fetches the relevant history records, ensuring they are sorted so that the most recent changes appear first.
4. Metadata Calculation: The system counts the total number of history records available to help the user navigate through the pages (e.g., calculating the total number of pages).
5. Response: The system returns the requested list of changes along with helpful information about the current page and total record count.

2.3 Key Concepts

- Audit Trail: A historical record of changes, allowing users to track who modified supplier information and what those changes were.
- Pagination: A method of breaking a large list of records into smaller, manageable chunks (pages) to improve performance and readability.
- Access Control: A security measure that ensures users can only view data belonging to their own company, preventing unauthorized access to sensitive supplier information.
- Metadata: Supporting information returned with the data, such as the total number of pages, which helps the user interface display navigation controls correctly.

2.4 Business Value

This feature improves transparency and accountability within the Lumi ERP system. By providing a clear history of supplier updates, businesses can easily track modifications, troubleshoot data discrepancies, and maintain a

reliable audit trail for compliance and operational oversight. The use of pagination ensures that even suppliers with extensive change histories can be reviewed efficiently without overwhelming the system or the user.

BUSINESS REQUIREMENTS DOCUMENT

Deactivate Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Deactivate Supplier feature provides a safe way to manage supplier status within the Lumi ERP system. When a user initiates the deactivation process, a confirmation window appears to prevent accidental changes. This ensures that users intentionally verify their decision before the system updates the supplier's status.

1.2 Step-by-Step Flow

1. Initiation: The user triggers the deactivation process for a specific supplier.
2. Confirmation: A modal window appears asking, "Are you sure?" to confirm the action.
3. User Choice:

* If the user selects Cancel, the window closes, and no changes are made.

* If the user selects OK, the system proceeds to update the supplier's status.

4. Processing: The system automatically flips the supplier's current status (e.g., changing an active supplier to inactive).
5. Completion: Once the update is successfully processed, the modal closes, and the supplier list is updated to reflect the new status.

1.3 Key Concepts

- Confirmation Modal: A pop-up window designed to act as a safety net, requiring the user to confirm an action before it is finalized.
- Status Toggle: The logic that automatically switches a supplier's status to the opposite of its current state (Active becomes Inactive, and vice versa).
- Error Handling: If the system encounters an issue while updating the status, an error message will appear within the modal to inform the user.

1.4 Business Value

This feature improves data integrity and user experience by reducing the risk of human error. By requiring a deliberate confirmation step, the system prevents accidental deactivations that could disrupt supply chain operations. Additionally, the automated status-flipping logic simplifies the workflow for administrators, allowing them to manage supplier availability quickly and accurately without manual data entry.

2. Logic

2.1 Overview

The "Deactivate Component" feature allows users to easily toggle the status of a supplier within the Lumi ERP system. By clicking the "OK" button in the confirmation modal, the system automatically flips the supplier's current status—deactivating an active supplier or reactivating one that was previously inactive. The system is designed to handle these updates reliably, ensuring the user interface stays synchronized with the actual data.

2.2 Step-by-Step Flow

1. Initiation: The user selects a supplier and clicks the "OK" button in the confirmation modal to proceed with the status change.
2. Processing: The system locks the button to prevent accidental duplicate requests while it communicates with the server.
3. Status Update: The system sends a request to the server to invert the supplier's current status (e.g., changing "Active" to "Inactive").
4. Success Handling: If the server confirms the update, the modal closes automatically, and the main supplier list refreshes to display the new status.
5. Error Handling: If the update fails for any reason, the modal remains open, the supplier's status remains unchanged, and an error message is displayed to inform the user of the issue.

2.3 Key Concepts

- Toggle Logic: A simple "on/off" mechanism that automatically detects the current state of a supplier and switches it to the opposite state.
- Processing State: A safety feature that prevents the user from clicking the button multiple times while the system is busy, which helps avoid data errors.
- Data Synchronization: The process of ensuring that the list of suppliers shown on the screen always matches the most current information stored in the database.
- Error Resilience: A design approach that keeps the user informed and prevents data loss by keeping the modal open if a request fails, allowing the user to try again or investigate the error.

2.4 Business Value

This feature streamlines supplier management by providing a quick, intuitive way to update supplier availability. By automating the status toggle and ensuring the interface remains consistent with the backend, the system reduces manual effort and minimizes the risk of human error. The built-in error handling and processing safeguards ensure that the user experience remains stable and reliable, even if network or server issues occur.

3. Data

3.1 Overview

The "Deactivate Supplier" feature allows users to officially mark a supplier as inactive within the Lumi ERP system. This process ensures that the system accurately reflects which suppliers are no longer in use, preventing them from being accidentally selected for new business activities while maintaining their historical records.

3.2 Step-by-Step Flow

1. Selection: The user selects a specific supplier from the supplier list.
2. Verification: The system retrieves the current details of the selected supplier to confirm their identity and current status before proceeding.
3. Deactivation Request: Once confirmed, the system sends a request to update the supplier’s status to "inactive."
4. Status Update: The system processes the request, effectively removing the supplier from active status in the database.

3.3 Key Concepts

- Supplier: A business entity or vendor managed within the ERP system.
- Deactivation: The process of changing a supplier's status to "inactive," which effectively archives them without deleting their historical data.
- Status Verification: A safety check performed by the system to ensure the correct supplier record is being modified.

3.4 Business Value

This feature provides better data integrity and operational control. By allowing users to deactivate suppliers, the organization can clean up its active vendor list, reduce the risk of errors (such as placing orders with a discontinued supplier), and ensure that reporting remains accurate by focusing only on currently active business partners.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Details Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier Details Card is a read-only component designed for the Supplier Detail Page within the Lumi ERP system. Its primary purpose is to provide a clear, organized view of a supplier's identity and contact information, ensuring that users can quickly reference essential business data without the risk of accidental modification.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "Details" header accompanied by a person icon to clearly identify the section's purpose.
2. Identity Information: The system populates the card with the supplier's name, unique supplier code, and the designated contact person's name.
3. Contact Information: The system displays the supplier's email, phone number, fax number, and physical address.
4. Tax & Registration: The system displays the Tax Number and Registration Number. These specific fields include a help icon to provide additional context or guidance to the user if needed.
5. Empty State Handling: If any specific piece of information is missing for a supplier, the system will display a dash (-) to maintain a clean and consistent layout.

1.3 Key Concepts

- Read-Only Fields: Information displayed for reference purposes only; users cannot edit or change these values directly within this component.
- Help Icons: Visual indicators placed next to complex or specific fields (Tax and Registration numbers) that allow users to access additional information or definitions.
- Data Grid: A structured layout that groups related information (Identity, Contact, and Tax/Registration) to improve readability and user experience.

1.4 Business Value

This component centralizes critical supplier data, reducing the time users spend searching for contact or tax information. By presenting this data in a standardized, read-only format, the feature minimizes the risk of data entry errors and ensures that all team members are viewing consistent, accurate information when managing supplier relationships.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier Settings Card is a read-only component located on the Supplier Detail page. Its purpose is to provide a quick, at-a-glance summary of a supplier’s operational status and their associated accounting configurations. This card ensures that users can easily verify key supplier settings without needing to navigate through multiple screens or edit records.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "Settings" header accompanied by a gear icon to clearly identify the section.
2. Status Flag Review: The system displays three primary status indicators: whether the supplier is active, whether they are permitted to receive store purchase orders, and whether they are classified as an internal supplier.
3. Visual Status Indicators: For each status flag, the system uses a green checkmark icon to indicate a "Yes" status and a red "X" icon to indicate a "No" status.
4. Contextual Help: Each status flag includes a help icon that, when interacted with, provides additional information about what that specific setting represents.
5. Accounting Data Display: The card lists specific accounting details, including sales tax information and various accounts payable (AP) and deposit account designations, presented in a clear, read-only format.

1.3 Key Concepts

- Read-Only: Information is displayed for reference purposes only and cannot be modified directly within this card.
- Status Flags: Boolean indicators (Yes/No) that use color-coded icons to help users instantly identify the operational state of a supplier.
- Tooltip: A small informational pop-up triggered by the help icon that provides clarity on the purpose of specific settings.
- Accounting Accounts: Specific financial categories (such as deposit, down payment, and invoice accounts) that define how transactions with this supplier are handled in the system.

1.4 Business Value

This feature improves operational efficiency by centralizing critical supplier information in one location. By providing immediate visibility into status flags and accounting settings, it reduces the time staff spend searching for data, minimizes the risk of errors during procurement, and ensures that users have the necessary context to make informed decisions when managing supplier relationships.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Notes Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier Notes Card is a dedicated section within the Supplier Detail page designed to provide quick, read-only access to critical reference information. It centralizes the supplier's banking information and any relevant operational notes, ensuring that team members have immediate visibility into these details without needing to navigate away from the supplier's profile.

1.2 Step-by-Step Flow

1. Loading State: When you first open the supplier page, the system briefly displays a loading indicator while it retrieves the necessary information from the database.
2. Data Retrieval: The system automatically fetches the specific bank details and notes associated with the selected supplier.
3. Displaying the Header: The card appears with a "Note" header, accompanied by a document icon to help you quickly identify this section.
4. Presenting Bank Details: The system displays the supplier's banking information in a clear, read-only format.
5. Presenting Operational Notes: The system displays any additional free-text notes regarding the supplier (such as specific engine parts or service requirements) in a read-only format below the bank details.
6. Error Handling: If the system is unable to retrieve the information due to a connection issue, a clear error message is displayed to inform you that the data could not be loaded.

1.3 Key Concepts

- Read-Only: Information that is displayed for your reference but cannot be edited directly within this specific card.
- Supplier Data: The centralized information stored in our system regarding a specific vendor, including their financial and operational details.
- Loading State: A temporary visual indicator that lets you know the system is actively working to retrieve information.

1.4 Business Value

This feature improves operational efficiency by eliminating the need to search through separate documents or external files to find banking or account-specific notes. By surfacing this information directly on the Supplier Detail page, team members can make faster, more informed decisions during procurement or payment processes, while the read-only nature of the data ensures that sensitive information remains accurate and protected from accidental changes.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Prices Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Prices" card is a dedicated section within the Supplier Details page designed to provide quick visibility into the pricing configuration assigned to a specific supplier. This component ensures that users can easily identify which price list is currently active for a supplier without needing to navigate away from the main profile view.

1.2 Step-by-Step Flow

1. Loading State: When the page first loads, the system displays a temporary loading indicator to ensure a smooth visual experience while the data is being retrieved.
2. Data Retrieval: The system automatically fetches the specific price list configuration associated with the current supplier.
3. Displaying Information: Once the data is retrieved, the card displays the assigned price list name.
4. Handling Missing Data: If no price list is assigned to the supplier, the system will display a clear "No price list assigned" message instead of leaving the field blank.
5. Read-Only Access: The price list information is presented in a read-only format, ensuring that the data cannot be accidentally modified from this view.

1.3 Key Concepts

- Read-Only Field: A display element that allows users to view information without the ability to edit or change it, ensuring data integrity.
- Loading State: A visual placeholder shown while the system is communicating with the database, which prevents the page layout from jumping or shifting unexpectedly.
- Placeholder Text: A user-friendly label that appears when specific data is missing, providing clarity rather than showing an empty or confusing field.

1.4 Business Value

This feature improves operational efficiency by centralizing critical supplier information. By providing a clear, read-only view of the active price list, procurement and administrative staff can verify supplier terms instantly. This reduces the need to search through secondary documents or separate systems, minimizing the risk of errors during the purchasing process.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Changes Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Changes" card is a dedicated section on the Supplier Detail page designed to provide transparency regarding the history of a supplier record. It acts as an audit trail, allowing users to quickly identify when a record was first created, when it was last modified, and which users performed these actions.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "Changes" title accompanied by a clock icon to clearly signal that this section contains historical audit information.
2. Creation Details: The system displays the exact date and time the supplier record was first created, alongside the name of the user who performed the creation.
3. Update Details: The system displays the date and time of the most recent modification to the record, alongside the name of the user who made the last update.
4. Visual Formatting: All dates are automatically converted into a consistent, easy-to-read format (e.g., 02-Dec-2024 11:10 AM), and all information is presented in a read-only format to distinguish it from editable data fields.

1.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific data record.
- Read-Only Fields: Information displayed for reference purposes that cannot be modified by the user, ensuring the integrity of the historical data.
- Standardized Formatting: A uniform way of presenting dates and times to ensure clarity and consistency across the entire application.

1.4 Business Value

This feature improves data governance and accountability within the Lumi ERP system. By providing a clear history of who modified supplier information and when, teams can easily track changes, troubleshoot data discrepancies, and maintain a reliable audit trail for compliance and operational oversight.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Detail Menu

Prepared by Kolosal AI

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

1. Frontend

1.1 Overview

The Supplier Detail Menu is a navigation component designed to help users easily switch between different views of a supplier's profile. It acts as a central control panel on the supplier page, allowing users to toggle between general supplier information, product listings, and historical records without leaving the context of the supplier they are currently viewing.

1.2 Step-by-Step Flow

1. Initial Load: When a user first opens a supplier profile, the system automatically selects the "Supplier" tab as the default view.
2. User Interaction: The user selects one of the three available menu options: Supplier, Products, or History.
3. State Update: The system highlights the selected tab to provide visual feedback, indicating which section is currently active.
4. Navigation: The system updates the page content to display the specific information requested (e.g., switching from the main profile to the product list).

1.3 Key Concepts

- Active Tab State: A visual indicator that tracks which menu item the user is currently viewing, ensuring the user always knows their location within the supplier profile.
- Navigation Items: The three primary categories—Supplier, Products, and History—that organize the supplier data into logical, manageable sections.
- Seamless Switching: The ability to move between different data views instantly, which keeps the user focused on the specific supplier record they are investigating.

1.4 Business Value

This feature improves user efficiency by providing a clean, organized way to access supplier data. By grouping information into distinct categories, users can quickly find the specific details they need—such as checking a product list or reviewing past interactions—without navigating through cluttered screens. This streamlined experience reduces the time spent searching for information and helps maintain a consistent workflow when managing supplier relationships.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Details - Credit Terms Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Credit Terms Card is a dedicated section on the Supplier Detail page designed to provide a quick, clear view of the financial arrangements established with a specific supplier. This component displays the maximum credit amount allowed and the agreed-upon payment timeframe, ensuring that users have immediate access to this critical information without needing to navigate through complex menus.

1.2 Step-by-Step Flow

1. The system retrieves the supplier's financial profile from the database.
2. The Credit Terms Card component receives this data and displays the "Credit Terms" header with a visual icon for easy identification.
3. The system displays the Credit Limit, automatically formatted as Indonesian Rupiah (IDR) for readability.
4. The system displays the Credit Term, showing the number of days allowed for payment followed by the word "days."
5. All information is presented in a read-only format, ensuring the data remains secure and consistent while being viewed.

1.3 Key Concepts

- Credit Limit: The maximum monetary value of goods or services that the supplier allows the company to purchase on credit, displayed in local currency.
- Credit Term (Days): The specific number of days the company has to settle an invoice after a purchase is made.
- Read-Only: A display setting that allows users to view information clearly without the ability to edit or change the values directly from this card.

1.4 Business Value

This feature improves operational efficiency by centralizing essential financial data in one place. By providing an instant, accurate view of credit limits and payment terms, procurement and finance teams can make informed purchasing decisions, avoid exceeding credit limits, and better manage cash flow and payment schedules.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Form - Prices Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Prices Card" is a dedicated section within the Supplier Form designed to help you manage pricing details for your suppliers. It provides a clear, user-friendly interface to select the appropriate pricing list, define the unit cost, and specify the currency for a supplier's products. This component ensures that pricing data is captured accurately and consistently before it is saved to the system.

1.2 Step-by-Step Flow

1. Header Identification: The section is clearly marked with a "Pricing Configuration" header and a dollar icon, helping users quickly identify the purpose of the panel.
2. Pricelist Selection: You select the relevant pricelist from a dropdown menu. The system automatically defaults to your company's standard supply price to save time.
3. Unit Price Entry: You enter the specific unit price for the item. The system performs an immediate check to ensure the value is a valid number and is not negative, providing instant feedback if an error is detected.
4. Currency Specification: You define the currency associated with the price to ensure financial accuracy.
5. Data Submission: Once the information is entered, the system bundles these details and securely saves them to the supplier's profile.

1.3 Key Concepts

- Pricelist: A pre-defined set of pricing rules or tiers that can be applied to a supplier to ensure consistent billing.
- Immediate Validation: A safety feature that checks your input as you type, preventing errors (like entering a negative price) before you even attempt to save the form.
- Defaulting: The system automatically fills in fields with standard company values, reducing the amount of manual data entry required.

1.4 Business Value

- Data Accuracy: By validating price inputs in real-time, the system prevents common data entry errors that could lead to financial discrepancies.
- Efficiency: Defaulting to the company's standard pricelist speeds up the supplier onboarding and editing process.
- Clarity: The intuitive layout and clear labeling reduce the learning curve for staff, ensuring that pricing information is organized and easy to manage across all suppliers.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Form - Notes Tab Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier Notes & Banking card is a dedicated section within the supplier profile page. It provides a centralized space for users to record important contextual information and essential financial details for a supplier. This component ensures that all relevant administrative and payment-related data is easily accessible and kept up to date during the supplier management process.

1.2 Step-by-Step Flow

1. Display Header: The section is clearly labeled with a header and an icon, signaling to the user that this area is for supplementary supplier information.
2. Input Notes: The user enters free-text comments or context regarding the supplier into the designated notes area.
3. Input Bank Details: The user enters the necessary banking or payment account information into the provided field.
4. Real-time Validation: As the user types, the system automatically checks the length of the input. If the notes exceed 2,000 characters or the bank details exceed 500 characters, an error message appears immediately to guide the user.
5. Data Persistence: Once the user is satisfied with the entries, the information is saved to the system, ensuring the supplier record remains current.

1.3 Key Concepts

- Free-text Notes: A flexible input area designed for capturing qualitative information, such as communication history or specific supplier requirements.
- Bank Details: A structured field intended for storing payment-related information required for financial transactions.
- Input Validation: A safety feature that prevents data entry errors by enforcing character limits, ensuring the information fits within the system's storage requirements.
- Immediate Feedback: A user-experience design choice where the system alerts the user to errors as they happen, rather than waiting until the form is submitted.

1.4 Business Value

- Improved Data Accuracy: By enforcing character limits, the system ensures that critical banking and note information is captured in a format that is compatible with downstream financial processes.
- Centralized Information: Consolidating notes and banking details into one tab reduces the time spent navigating between different pages to find supplier context.

- Enhanced User Experience: Real-time validation reduces frustration by helping users correct input errors instantly, leading to a smoother and more efficient data entry process.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Form - Details Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Supplier Details Card is a user-friendly form component designed for the Lumi ERP system. It allows users to easily add or update supplier information. The form is built to ensure data quality by providing immediate feedback to the user if required information is missing or if an email address is formatted incorrectly.

1.2 Step-by-Step Flow

1. Data Entry: The user fills out the form fields, which include essential supplier identification, contact details, and location information.
2. Real-time Validation: As the user types or moves between fields, the system automatically checks the input.
3. Error Feedback: If a required field is left blank or an email address is invalid, the system immediately displays an error message to guide the user.
4. Form Submission: Once all required fields are correctly filled and no errors remain, the "Save" button becomes active.
5. Data Processing: Upon clicking "Save," the system securely transmits the completed supplier information to the database.

1.3 Key Concepts

- Required Fields: Specific information (Name, Contact Name, Phone Number, Address, and Country) that must be provided to successfully save a supplier record.
- Optional Fields: Additional details (such as Supplier Code, Email, Fax, Tax Number, and Registration Number) that can be provided if available but are not mandatory.
- Immediate Validation: A feature that checks the accuracy of the data as the user interacts with the form, preventing errors before the user attempts to save.
- Form State: The internal memory of the form that tracks all the information currently entered by the user before it is finalized.

1.4 Business Value

This component streamlines the supplier management process by reducing manual data entry errors. By enforcing validation at the point of entry, the system ensures that the ERP database maintains high-quality, reliable contact information. This ultimately saves time for administrative staff and improves the accuracy of downstream business operations, such as procurement and communication with suppliers.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Form - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Supplier Settings Card is a dedicated section within the Supplier management page. It provides a centralized area for users to configure key operational and accounting preferences for a specific supplier. This component ensures that essential business rules—such as tax settings, account mapping, and supplier status—are easily accessible and consistently applied during the supplier setup or editing process.

1.2 Step-by-Step Flow

1. Initialization: When the page loads, the system automatically retrieves the current list of financial accounts from the company's Chart of Accounts to populate the dropdown menus.
2. Configuration Toggles: The user interacts with three primary checkboxes to define the supplier's operational status:

* Active: Marks the supplier as currently enabled for business.

* Internal Supplier: Flags whether the supplier is an internal entity or an external vendor.

* Allow Store Purchase Order: Determines if individual stores are permitted to place purchase orders directly with this supplier.

3. Account Mapping: The user selects specific financial accounts for four distinct categories (AP Invoice, AP Credit Note, Down Payment, and Deposit) from the pre-loaded list.
4. Tax Selection: The user selects the appropriate sales tax rule for the supplier. This field is mandatory, with a default option to "Use Product Tax Rate" if no specific tax rule is required.
5. Submission: Once configured, all selected settings and account mappings are saved as part of the overall supplier record.

1.3 Key Concepts

- Chart of Accounts: The master list of financial accounts used by the organization to track money; these are used here to ensure accounting entries are mapped to the correct ledgers.
- Operational Toggles: Simple "Yes/No" switches that allow users to quickly enable or disable specific business capabilities for a supplier.
- Account Mapping: The process of linking a supplier to specific financial accounts, ensuring that transactions (like payments or deposits) are automatically categorized correctly in the accounting system.
- Mandatory Fields: Specific settings, such as the Sales Tax rule, that must be defined to ensure the supplier record is complete and compliant with financial reporting requirements.

1.4 Business Value

- Operational Efficiency: By grouping all configuration settings into one card, users can manage supplier preferences quickly without navigating through multiple screens.
- Data Accuracy: Automating the retrieval of the Chart of Accounts reduces manual entry errors, ensuring that financial transactions are always linked to valid, pre-approved accounts.
- Standardization: Providing clear, consistent toggles and dropdowns ensures that every supplier is set up with the same level of detail, which simplifies reporting and auditing across the organization.

2. Logic

2.1 Overview

The Supplier Settings Card is a component within the Supplier management page that allows users to define specific accounting behaviors for a supplier. It provides four dropdown menus where users can select the appropriate financial accounts for different types of transactions, such as purchases, credit notes, down payments, and deposits. This ensures that all financial activity related to a specific supplier is automatically mapped to the correct ledger accounts.

2.2 Step-by-Step Flow

1. Data Loading: When the page loads, the system automatically fetches the current list of available financial accounts from the company's Chart of Accounts.
2. Display Formatting: The system takes the raw account data and formats it into a user-friendly list, showing both the account code and the account name (e.g., "1001 - Inventory Purchases") so users can easily identify the correct option.
3. User Selection: The user selects the relevant account for each of the four categories: AP Invoice, AP Credit Note, Supplier Down Payment, and Supplier Deposit.
4. State Management: As the user makes selections, the system tracks these choices in the background, linking the selected account's unique identifier to the specific supplier setting.
5. Submission: When the supplier form is saved, these selected account identifiers are bundled with the rest of the supplier information to ensure the settings are applied correctly in the system.

2.3 Key Concepts

- Chart of Accounts (COA): The master list of financial accounts used by the business to categorize transactions.
-

Dropdown Mapping: The process of taking a list of accounts and presenting them in a menu so that a user can pick one, while the system remembers the underlying ID of that account.

- Account Identifier: A unique internal code used by the software to ensure that the correct financial account is referenced, regardless of how the account name is displayed to the user.
- Supplier Settings: Specific configurations that dictate how the system handles financial transactions for a particular supplier, ensuring consistency in accounting records.

2.4 Business Value

- Accuracy: By providing a standardized list of accounts, the system reduces the risk of manual data entry errors when assigning financial categories to suppliers.
- Efficiency: Users can quickly configure supplier settings using pre-populated dropdowns rather than searching for or typing in account details manually.
- Consistency: Automating the link between suppliers and their respective financial accounts ensures that all accounting reports and financial statements remain accurate and reliable.

3. Data

3.1 Overview

The Supplier Settings Card is a new component within the Supplier management page that allows users to define specific accounting behaviors for each supplier. By selecting the appropriate accounts from the Chart of Accounts, users can ensure that financial transactions—such as invoices, credit notes, down payments, and deposits—are automatically mapped to the correct ledger accounts.

3.2 Step-by-Step Flow

1. Data Retrieval: When the page loads, the system fetches the current list of available accounts from the Chart of Accounts.
2. Formatting: The system organizes this list so that each option is clearly displayed as a combination of the account code and the account name, making it easy for users to identify the correct selection.
3. User Selection: The user interacts with four distinct dropdown menus, each representing a specific financial category (AP Invoices, Credit Notes, Down Payments, and Deposits).
4. State Management: As the user selects an account for each category, the system tracks these choices in the background.
5. Submission: When the user saves the supplier form, these four account selections are bundled with the rest of the supplier data and sent to the system to update the supplier's financial settings.

3.3 Key Concepts

- Chart of Accounts (COA): The master list of financial accounts used by the organization to categorize transactions.
- Dropdown Mapping: The process of linking a user-friendly label (Account Code + Name) to a unique system identifier (Account ID) to ensure accurate data processing.
- Financial Categories: The four specific areas (AP Invoices, Credit Notes, Down Payments, and Deposits) where the system needs to know which ledger account to use for that specific supplier.

3.4 Business Value

- Accuracy: By allowing users to pre-select specific accounts for supplier transactions, the system reduces the risk of manual data entry errors during the accounting process.
- Efficiency: Automating the mapping of supplier-related financial activities saves time for the accounting team, as they no longer need to manually reclassify these transactions later.
- Consistency: Ensures that all financial activity related to a specific supplier is consistently recorded in the correct ledger, providing cleaner and more reliable financial reporting.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Form - Credit Terms Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Credit Terms card is a dedicated section within the supplier management page designed to help you standardize financial agreements with your suppliers. This feature allows you to clearly define how long a supplier has to pay an invoice and set a maximum spending limit, ensuring that your financial data is captured accurately and consistently during the supplier onboarding or editing process.

1.2 Step-by-Step Flow

1. Section Identification: The user navigates to the "Credit Terms" section, which is clearly marked with a credit card icon for quick visual recognition.
2. Defining Payment Duration: The user enters the number of days allowed for payment in the "Credit Term (Days)" field. If the user needs clarification, they can hover over or tap the question mark icon to see a helpful explanation of this field.
3. Setting Credit Limits: The user enters an optional maximum credit limit for the supplier to help manage financial exposure.
4. Real-time Validation: As the user types, the system automatically checks the entries. If a user enters a non-positive number for the payment duration or a negative number for the credit limit, the system immediately displays an error message to prevent incorrect data entry.

1.3 Key Concepts

- Credit Term (Days): The specific timeframe (in days) granted to a supplier to settle their invoices after receipt. This is a mandatory field.
- Maximum Credit Limit: An optional financial ceiling that restricts the total amount of credit extended to a supplier.
- Input Validation: An automated safety check that ensures all entered numbers are logical (e.g., preventing negative credit limits) before the form is submitted.
- Contextual Tooltip: A helpful "question mark" icon that provides on-demand guidance to the user, reducing the need for external documentation.

1.4 Business Value

- Data Accuracy: By enforcing validation rules at the point of entry, the system prevents common human errors, such as entering negative values or missing mandatory payment terms.
- Improved Efficiency: The inclusion of tooltips and clear labeling reduces user confusion, allowing staff to complete supplier profiles faster and with more confidence.
-

Financial Control: Standardizing how credit terms and limits are recorded provides better visibility into your company's financial commitments and helps maintain consistent credit policies across all supplier relationships.

BUSINESS REQUIREMENTS DOCUMENT

Supplier List JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Supplier List feature provides a structured way to manage and retrieve supplier information within the Lumi ERP system. It allows users to search, filter, and view supplier details, as well as update the status (active or inactive) of specific suppliers. All operations are strictly scoped to the user's company to ensure data security and relevance.

1.2 Step-by-Step Flow

1. List Retrieval: When viewing the supplier list, the system accepts optional filters (such as name, phone, or status) and pagination settings (limit and offset) to return a manageable set of supplier records.
2. Detailed View: Users can request the full profile of a specific supplier by providing a unique identifier. This returns comprehensive information, including contact details, tax settings, credit terms, and accounting references.
3. Status Management: Users can update a supplier's status (e.g., marking them as inactive) by sending a request with the new status. The system confirms the update by returning the supplier's ID and the timestamp of the change.
4. Quick Lookup: For scenarios requiring only names (such as dropdown menus), the system provides a lightweight list of active supplier names, excluding unnecessary data to improve performance.

1.3 Key Concepts

- Filtering: The ability to narrow down the supplier list using specific criteria like `isinternal`, `suppliercode`, `name`, `contactname`, `phone`, or `isactive`.
- Pagination: A mechanism to control the volume of data returned in a single request by setting a `limit` (number of records) and an `offset` (where to start in the list).
- Company Scoping: A security measure that ensures users only interact with supplier data belonging to their own organization, automatically applied to all requests.
- Status Toggle: A specific action to change a supplier's `is_active` state, which helps maintain accurate records without deleting historical data.

1.4 Business Value

- Operational Efficiency: By providing flexible search and filtering, staff can quickly locate specific suppliers, reducing time spent navigating large datasets.
- Data Integrity: The system ensures that sensitive supplier information—such as tax numbers, credit limits, and accounting references—is retrieved and updated in a controlled, consistent manner.
-

Performance Optimization: The inclusion of a "names-only" lookup feature ensures that common tasks, like selecting a supplier from a list, remain fast and responsive.

- Security: Automatic company scoping prevents accidental cross-company data access, maintaining strict organizational boundaries.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Detail JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Supplier Detail feature provides a comprehensive view of a specific supplier's information within the Lumi ERP system. When a user requests to view a supplier, the system retrieves all relevant data—including contact details, financial settings, and accounting configurations—and combines it with descriptive names from related system records to ensure the information is easy to read and understand.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a specific supplier, identified by a unique ID, and ensures the request is scoped to the user's current company.
2. Data Retrieval: The system queries the main supplier database for all stored attributes, such as contact information, credit terms, and tax settings.
3. Information Enrichment: To make the data more user-friendly, the system automatically looks up and attaches human-readable names for various linked records (such as the names of tax categories, specific accounting accounts, and the users who created or last updated the record).
4. Response Formatting: The combined data is structured into a standardized format (JSON) that ensures all required fields are present and correctly labeled for the user interface.

1.3 Key Concepts

- Supplier Record: The central profile containing identity, contact, and operational settings for a business partner.
- Foreign Key Resolution: The process of replacing internal system IDs (which are just strings of characters) with the actual, recognizable names of related items (e.g., showing "Standard Tax" instead of a random ID code).
- Data Scoping: A security measure that ensures users can only access supplier information that belongs to their specific company.
- Accounting References: Specific links to the Chart of Accounts that define how transactions with this supplier (like purchases or deposits) should be categorized in the company's financial records.

1.4 Business Value

- Improved Data Clarity: By automatically resolving IDs into readable names, users can instantly identify tax settings, pricelists, and accounting accounts without needing to cross-reference other parts of the system.
- Operational Efficiency: Centralizing all supplier-related data—from contact info to financial and accounting settings—into a single view allows staff to manage supplier relationships and financial compliance more quickly.
-

Data Integrity: The standardized structure ensures that every supplier record is displayed consistently, reducing the risk of errors when viewing or updating supplier details.

BUSINESS REQUIREMENTS DOCUMENT

Supplier Edit JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The "Supplier Edit" feature allows authorized users to update existing supplier information within the Lumi ERP system. This ensures that contact details, credit terms, and financial account mappings remain accurate and up-to-date. The system enforces strict data validation to ensure that essential information—such as the supplier's name and credit terms—is always provided.

1.2 Step-by-Step Flow

1. Initiation: A user opens the "Edit Supplier" page and submits updated information for a specific supplier.
2. Validation: The system checks the submitted data against a predefined set of rules (the JSON Schema) to ensure all required fields are present and formatted correctly.
3. Security & Scoping: The system identifies the specific supplier using a unique ID and ensures the update is restricted to the user's current company.
4. Processing: The system updates the supplier record in the database, automatically recording which user performed the update.
5. Confirmation: Once the update is successful, the system returns the full, updated supplier record to confirm the changes were saved.

1.3 Key Concepts

- JSON Schema: A set of rules that defines what information is required (e.g., name, address) and how it must be formatted (e.g., email addresses, numeric credit limits) before the system will accept an update.
- Data Scoping: A security measure that ensures users can only edit suppliers that belong to their own company, preventing unauthorized access or accidental cross-company data modification.
- Audit Trail: The system automatically tracks the "updaterid" (who made the change) and the "updatedat" timestamp, providing accountability for all modifications.
- Required Fields: Specific pieces of information, such as the supplier's name and credit terms, that must be provided for every supplier record to maintain operational integrity.

1.4 Business Value

- Data Accuracy: By enforcing validation rules, the system prevents incomplete or incorrectly formatted data from entering the ERP, which reduces errors in procurement and accounting.
- Operational Efficiency: Users can quickly and reliably update supplier details, ensuring that financial and contact information is always current for daily operations.
-

Security & Compliance: By scoping updates to the user's company and tracking who performed each update, the system maintains a secure and auditable record of all changes, which is essential for financial reporting and internal controls.

BUSINESS REQUIREMENTS DOCUMENT

Supplier History JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Supplier History feature provides a transparent audit trail of changes made to a supplier's profile. By tracking modifications to key information—such as contact details, tax numbers, and credit terms—this feature allows users to see exactly what was changed, when it was updated, and who performed the update. This ensures accountability and helps maintain accurate records within the Lumi ERP system.

1.2 Step-by-Step Flow

1. Request: The system receives a request for the history of a specific supplier.
2. Data Retrieval: The system fetches the relevant change records from the database, specifically filtering for the requested supplier.
3. Sorting: The records are organized so that the most recent changes appear at the top of the list.
4. Pagination: The system calculates the total number of records and pages to ensure the data is presented in manageable chunks, rather than loading everything at once.
5. Response: The system returns a structured summary containing the requested page of history records, along with metadata (such as total page count) to help the user navigate the history list.

1.3 Key Concepts

- Audit Trail: A chronological record of changes that provides evidence of who modified supplier data and when those changes occurred.
- Pagination: A method of breaking a large list of records into smaller, easier-to-read pages to improve system performance and user experience.
- Supplier Profile Fields: The specific data points being tracked, including contact information (address, phone, email), business identifiers (tax and registration numbers), and financial settings (credit terms and limits).
- Metadata: Supporting information returned with the data, such as the current page number and total number of available pages, which helps the interface display navigation controls correctly.

1.4 Business Value

- Accountability: By logging who updated a supplier record, the organization can easily identify the source of data changes.
- Data Integrity: Having a clear history of modifications helps teams troubleshoot errors or discrepancies in supplier information.
- Compliance: Maintaining a reliable audit log is essential for financial and operational transparency, ensuring that changes to sensitive data like credit limits are documented and traceable.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales/ecommerce

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a dedicated way for the Lumi ERP system to retrieve a list of sales specifically generated through your ecommerce channels. It allows users to pull sales data in a controlled, paginated format, ensuring that only relevant ecommerce transactions are returned. The system includes built-in security checks and error handling to ensure data integrity and authorized access.

1.2 Step-by-Step Flow

1. Security Verification: The system first checks if the user has an active, valid session. If the session is missing or invalid, the request is rejected.
2. Parameter Processing: The system collects your search criteria (such as specific customer IDs or sale statuses). If you do not specify how many records to return or where to start, the system automatically defaults to showing the 20 most recent sales.
3. Data Retrieval: The system filters the database to include only sales marked as "ecommerce." It then applies your specific filters and sorts the results by the date they were created, showing the newest sales first.
4. Response Delivery:

* If successful, the system returns the requested list of sales, including details like the sale amount, currency, status, and customer information.
* If the request contains invalid information (such as a malformed ID), the system returns a "Bad Request" error.
* If an unexpected system error occurs, the system returns a general server error message.

1.3 Key Concepts

- Pagination: A method of breaking large lists of data into smaller, manageable chunks (using "limit" and "offset") to improve performance and readability.
- Filtering: The ability to narrow down the list of sales by specific criteria, such as a particular customer or the current status of an order.
- Session Validation: A security gate that ensures only authenticated users can access the sales data.
- Source Scoping: An internal rule that automatically restricts the search to "ecommerce" sales, preventing other types of sales data from appearing in these results.

1.4 Business Value

This feature enables your team to programmatically access ecommerce sales data directly within the ERP. By providing a standardized, filterable list, it simplifies reporting and order management workflows. The inclusion

of pagination and default sorting ensures that the system remains fast and responsive, even as your volume of ecommerce transactions grows, while the built-in security ensures that sensitive sales data remains protected.

2. Data

2.1 Overview

The `GET /api/sales/ecommerce` feature provides a dedicated way to retrieve sales data specifically generated through your e-commerce channels. This tool allows users to pull a list of transactions, apply specific filters to narrow down the results, and view the data in a clean, organized format. It is designed to be consistent with existing sales reporting tools within the Lumi ERP system.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to list e-commerce sales.
2. Data Scoping: The system automatically filters the database to include only records marked as "ecommerce."
3. Applying Filters: If provided, the system applies optional filters for a specific date range (start and end dates) and transaction status.
4. Sorting and Pagination: The system organizes the results by date (newest first). By default, it displays 20 records at a time, starting from the first record, unless different limits or offsets are requested.
5. Data Formatting: The raw database information is transformed into a standardized, easy-to-read format containing key details like the sale amount, currency, status, and customer ID.
6. Response: The final list is delivered to the user.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable pages (defaulting to 20 items) to ensure the system remains fast and responsive.
- Filtering: The ability to narrow down search results based on specific criteria, such as a date range or the current status of a sale.
- Sorting: The automatic arrangement of data in a specific order; in this case, the most recent sales appear at the top of the list.
- Data Mapping: The process of taking raw internal data and converting it into a clean, consistent structure that is ready for display or use by other applications.

2.4 Business Value

This feature enables the sales and operations teams to gain clear visibility into e-commerce performance without manual data extraction. By providing a standardized, filterable list, users can quickly track revenue, monitor order statuses, and perform audits on e-commerce activity. The consistent design ensures that teams familiar with other sales reporting tools in the Lumi ERP can use this feature immediately with no additional training.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. LOGIC

1.1 Overview

The Sales API feature provides a secure way for authorized users to browse and retrieve a list of retail store sales. It is designed to automatically filter data based on the user's current company and store, ensuring that users only see relevant, active point-of-sale (POS) transactions.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies the user's session. If the user is not logged in or the session is invalid, the request is rejected.
2. Scope Application: The system automatically identifies the user's company and store. It restricts the search to only include "POS" sales that have not been voided or cancelled.
3. Parameter Processing: The system processes any optional filters provided by the user, such as a specific salesperson or a date range. It also applies default settings (showing 20 results at a time, starting from the most recent).
4. Data Retrieval: The system queries the database using the applied scope, filters, and pagination settings.
5. Response: The system returns the requested list of sales. If the request contains invalid information, an error message is provided.

1.3 Key Concepts

- Authentication: A security check that ensures only verified users can access sales data.
- Scope: A built-in restriction that automatically limits results to the user's specific store and company, preventing unauthorized access to other locations' data.
- Pagination: A method of breaking large lists of data into smaller, manageable chunks (defaulting to 20 items) to improve performance and readability.
- Filtering: The ability to narrow down the list of sales by specific criteria, such as the date the sale occurred or the salesperson who processed it.
- Voided Sales: Transactions that have been cancelled; these are intentionally excluded from this list to ensure users only see active, valid sales records.

1.4 Business Value

This feature enables store managers and staff to efficiently monitor daily retail performance. By providing a filtered, paginated, and secure view of sales data, it allows for quick reporting and oversight of store activity without exposing sensitive data from other locations or including irrelevant cancelled transactions.

2. DATA

2.1 Overview

The Sales API feature provides a secure way for authorized users to retrieve and browse a list of retail store sales. It is designed to automatically filter data based on the user's current company and store, ensuring that users only see relevant, active Point-of-Sale (POS) transactions. The system includes flexible search and filtering options to help users quickly locate specific sales records.

2.2 Step-by-Step Flow

1. Authentication & Scope: The system verifies the user's session. It automatically restricts the search to the user's specific company and store, and only includes active "Point-of-Sale" transactions (excluding any that have been voided).
2. Applying Filters: The system checks for any optional search criteria provided by the user, such as specific document numbers, customer names, vehicle registrations, or sales staff IDs.
3. Date Range Selection: The user can narrow down results by a date range. They can choose to filter by either the date the sale was created or the date it was completed.
4. Formatting Results: The system organizes the final list by sorting it from the most recent to the oldest sale. It then presents the data in manageable "pages" (defaulting to 20 items per page) to ensure the information is easy to navigate.

2.3 Key Concepts

- Session Scope: A security measure that ensures users only access data belonging to their own company and store, preventing unauthorized data exposure.
- Dynamic Filtering: The ability for users to refine their search results using various criteria like customer name or status, without needing to see every record in the database.
- Pagination: A method of breaking a large list of records into smaller, manageable chunks (pages) to improve performance and readability.
- Workflow State: The current status of a sale (e.g., draft, pending, or completed). This feature specifically excludes "voided" sales to keep the list clean and focused on active business.

2.4 Business Value

This feature empowers store staff and managers to efficiently monitor and audit daily sales activity. By providing a fast, filterable, and secure interface, it reduces the time spent searching for transaction records and ensures that

reporting is based on accurate, active sales data. The automated scoping ensures data privacy and accuracy by design, reducing the risk of human error when accessing store information.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The `GET /api/sales-orders` feature provides a secure way for authorized users to retrieve a list of sales orders associated with their company. This tool is designed to be flexible, allowing users to search, filter, and organize large volumes of sales data efficiently through pagination and specific search criteria.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the user is logged in. If the user is not authenticated, the request is rejected.
2. Parameter Processing: The system collects the user's search and display preferences. If no specific preferences are provided, it defaults to showing the 20 most recent orders.
3. Validation: The system checks that all provided search criteria (such as dates or identification codes) are in the correct format. If the input is invalid, the system returns an error.
4. Data Retrieval: The system searches the company's sales records, applying any requested filters (like customer name, status, or date range) and sorting the results as requested.
5. Response: The system returns the filtered list of sales orders to the user. If an unexpected issue occurs during this process, the system provides an error notification.

1.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, manageable pages (controlled by "limit" and "offset") to improve performance.
- Filtering: The ability to narrow down the list of sales orders based on specific attributes, such as a date range, a specific warehouse, or the order status.
- Sorting: The ability to organize the results by a specific field (like the creation date) in either ascending or descending order.
- Authentication: A security check that ensures only users belonging to the correct company can access that company's private sales data.

1.4 Business Value

This feature empowers sales teams and managers to quickly access and analyze specific sales data without needing to manually sift through entire databases. By providing robust filtering and sorting capabilities, it enables faster decision-making, better tracking of order statuses, and improved visibility into company sales performance.

2. Data

2.1 Overview

The Sales Orders API feature allows users to retrieve a list of sales orders associated with their company. To ensure the system remains fast and easy to navigate, the results are provided in manageable "pages" rather than all at once. Users can narrow down their search using various criteria, such as specific dates, customer names, or order statuses, ensuring they find exactly the information they need.

2.2 Step-by-Step Flow

1. Security Check: The system verifies the user's identity to ensure they only access sales orders belonging to their specific company.
2. Filtering: The system applies any search criteria provided by the user (e.g., filtering by a specific salesperson or a date range).
3. Sorting: The system organizes the results based on the user's preference (defaulting to the most recently created orders).
4. Pagination: The system limits the number of results returned at one time (defaulting to 20 records) to keep the data transfer efficient.
5. Data Retrieval: The system gathers the requested records and provides a total count of all matching orders, allowing the user to navigate through multiple pages of results.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down a large dataset by specific attributes, such as status, customer, or date.
- Scoping: A security measure that automatically restricts data access so that users only see information relevant to their own company.
- Sorting: The process of arranging the list in a specific order, such as by date or document number, to help users find relevant information faster.

2.4 Business Value

This feature provides sales teams and managers with quick, reliable access to their order history. By offering flexible filtering and organized pagination, the system reduces the time spent searching for specific transactions. Furthermore, the built-in security scoping ensures that sensitive company data remains protected, providing a secure and efficient way to monitor sales performance and order fulfillment status.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-order/returns

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of sales order returns within the Lumi ERP system. It is designed to be used by the application's interface to display return records, allowing users to search, filter, and organize the data efficiently. The system automatically ensures that users can only view return records associated with their own company.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the user is logged in. If not, the request is rejected.
2. Parameter Setup: The system identifies how to display the list. By default, it shows 20 items at a time, sorted by the most recently created records. Users can override these defaults to change the page size, starting point, or sorting order.
3. Filtering: The system applies any search criteria provided by the user, such as specific reference codes, customer names, warehouse locations, workflow statuses, or date ranges.
4. Data Retrieval: The system searches the database for records that match the company's ID and the applied filters.
5. Response: The system returns the requested list of sales order returns. If the request is invalid or a system error occurs, an appropriate error message is provided.

1.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, manageable pages (using "limit" and "offset") to improve performance and readability.
- Filtering: The ability to narrow down the list of returns based on specific criteria, such as finding all returns for a specific customer or within a certain date range.
- Sorting: The ability to organize the list by specific columns (like date or reference code) in either ascending or descending order.
- Scope: A security measure that ensures the data returned is restricted to the specific company the user belongs to, preventing unauthorized access to other companies' data.
- Workflow State: The current status of a return (e.g., pending, approved, or completed), which can be used to filter the list.

1.4 Business Value

This feature empowers staff to manage the returns process effectively by providing a searchable and organized view of all return activity. By allowing users to filter by date, customer, or status, the system reduces the time spent searching for specific documents, improves operational visibility into return trends, and ensures that sensitive company data remains secure and isolated.

2. Data

2.1 Overview

This feature provides a way for users to view a list of all sales order returns associated with their company. It is designed to be flexible, allowing users to search, filter, and organize the list to quickly find specific return records. The system automatically ensures that users only see data belonging to their own organization.

2.2 Step-by-Step Flow

1. Request Initiation: The user requests the list of sales order returns through the application interface.
2. Security Check: The system verifies the user's identity and ensures the request is scoped strictly to their company's data.
3. Applying Filters: The system applies any search criteria provided by the user, such as specific reference codes, customer names, warehouse locations, workflow statuses, or date ranges.
4. Sorting and Organization: The system sorts the results based on the user's preference (defaulting to the most recently created returns).
5. Pagination: The system retrieves a specific "page" of results (defaulting to 20 items at a time) to ensure the application remains fast and easy to navigate.
6. Data Delivery: The system returns the filtered, sorted, and paginated list of records to the user. If the request is invalid or an error occurs, the system provides an appropriate error message.

2.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down the list of returns based on specific criteria, such as date or status, to find relevant information faster.
- Data Scoping: A security measure that automatically restricts the data returned to only what belongs to the user's specific company.
- Sorting: The ability to arrange the list in a specific order (e.g., by date or reference code) to help users prioritize their work.

2.4 Business Value

This feature empowers sales and warehouse teams to efficiently manage the return process. By providing a searchable and organized view of all returns, staff can quickly track the status of items coming back into inventory, resolve customer issues faster, and maintain accurate records of return workflows without needing to manually sift through large volumes of data.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-deliveries?{field}={value}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a flexible way to search and retrieve specific sales delivery records from the Lumi ERP system. Instead of pulling all records at once, users can filter the list by providing specific criteria—such as a reference number, customer ID, or delivery status—allowing for faster and more precise data access.

1.2 Step-by-Step Flow

1. Request Submission: The user sends a request to the system, specifying the field they want to filter by (e.g., "status") and the corresponding value (e.g., "delivered").
2. Validation: The system checks the request to ensure the requested field is valid and supported for searching. If the field is unrecognized or missing, the system returns an error.
3. Data Search: If the request is valid, the system searches the database for all records that match the provided criteria.
4. Response Delivery:

* If matches are found, the system returns the relevant delivery details, including dates, IDs, and status.

* If no records match the criteria, the system informs the user that nothing was found.

* If a system error occurs, the user is notified that the request could not be processed.

1.3 Key Concepts

- Filter: A search criterion used to narrow down results, such as searching by a specific customer or a unique reference number.
- Sales Delivery: A record in the system that tracks the movement of goods from the warehouse to the customer.
- Query Parameters: The specific instructions added to the search request that tell the system exactly what information to look for.
- Validation: A safety check performed by the system to ensure that only recognized search fields are used, preventing errors and ensuring data integrity.

1.4 Business Value

This feature improves operational efficiency by allowing staff to quickly locate specific delivery information without manual searching. By enabling targeted lookups—such as finding all deliveries for a specific warehouse or checking the status of a particular order—the system supports faster customer service responses and better inventory tracking.

2. Data

2.1 Overview

The Sales Delivery Search API allows users to quickly locate specific delivery records within the Lumi ERP system. Instead of browsing through a long list of deliveries, users can apply specific filters—such as a reference number, customer name, or delivery status—to retrieve only the information they need.

2.2 Step-by-Step Flow

1. Request Initiation: The user sends a request to the system specifying one or more search criteria (e.g., "show me all deliveries for Customer X with a status of 'delivered'").
2. Filter Application: The system reviews the request and identifies which filters are being applied. It maps these requests to the corresponding data fields in the database.
3. Data Retrieval: The system searches the database for records that match all the provided criteria. This includes support for specific date ranges (e.g., deliveries between two dates).
4. Response Delivery:

* If matches are found, the system returns the relevant delivery records.

* If no records match the criteria, the system informs the user that nothing was found.

* If the request is invalid or the user lacks the necessary permissions, the system returns an error message explaining the issue.

2.3 Key Concepts

– Filters: Specific criteria used to narrow down search results, such as reference numbers, customer IDs, or warehouse locations.

– Date Range Filtering: A feature that allows users to search for deliveries that occurred within a specific timeframe by providing a start date and an end date.

– Status: A category assigned to a delivery (e.g., "pending," "in transit," or "delivered") that can be used to filter search results.

– API Endpoint: The digital "address" that the software uses to request and receive delivery information from the database.

2.4 Business Value

This feature significantly improves operational efficiency for sales and logistics teams. By enabling precise, targeted searches, staff can:

* Reduce Administrative Time: Quickly find the status of a specific order without manual searching.

* Improve Customer Service: Provide immediate, accurate updates to customers regarding their delivery status.

* Enhance Reporting: Easily pull data for specific time periods or specific customers to support better business decision-making.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-deliveries

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way to retrieve a list of sales delivery records from the Lumi ERP system. It allows users to view details such as delivery dates, current statuses, and tracking numbers. Users can either request a full list of deliveries or narrow down the results by searching for a specific order ID.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and authorized to access delivery information.
2. Filter Application: The system checks if a specific order ID was provided to narrow the search.
3. Data Retrieval: The system searches the database for delivery records that match the request criteria.
4. Result Validation: If no records are found that match the criteria, the system informs the user that no results are available.
5. Data Delivery: If records are found, the system returns the relevant details, including the delivery date, status, and tracking information.
6. Error Handling: If an unexpected issue occurs during the process, the system provides an error message to ensure the user is aware of the failure.

1.3 Key Concepts

- Sales Delivery: A record representing the shipment of an order, containing key information like the tracking number and delivery status.
- Order ID: A unique identifier used to filter delivery records so that a user can find information related to one specific customer order.
- Authentication: The security process that ensures only verified users can access sensitive sales and shipping data.
- Status: The current state of a delivery (e.g., pending, in transit, or delivered), which helps users track the progress of their shipments.

1.4 Business Value

This feature improves operational efficiency by providing quick, self-service access to shipping information. By allowing staff to look up delivery statuses and tracking numbers instantly—either in bulk or by specific order—the business can reduce manual inquiries, improve customer communication regarding order arrivals, and maintain better visibility into the fulfillment process.

2. Data

2.1 Overview

The `GET /api/sales-deliveries` feature allows users to retrieve a list of sales delivery records from the Lumi ERP system. This tool is designed to help sales and logistics teams monitor the status of their shipments by providing flexible search options, such as filtering by delivery status or specific date ranges.

2.2 Step-by-Step Flow

1. Request Validation: The system checks the incoming request to ensure that all search criteria (such as date formats or status labels) are correctly formatted. If the information is invalid, the system alerts the user.
2. Data Retrieval: The system searches the database for delivery records that match the user's requested filters.
3. Sorting and Organization: The results are automatically sorted by the most recent delivery date first.
4. Pagination: To ensure the system remains fast and easy to navigate, the results are provided in manageable chunks (pages) rather than all at once.
5. Result Delivery:

– If matching records are found, the system returns the list to the user.

– If no records match the criteria, the system informs the user that no results were found.

2.3 Key Concepts

– Filtering: The ability to narrow down a large list of deliveries by specific criteria, such as "Pending" or "Delivered" status, or a specific timeframe.

– Pagination: A method of breaking a large list of data into smaller, readable pages to improve performance and user experience.

– Validation: A safety check performed by the system to ensure that the user's search request is logical and formatted correctly before processing it.

– Sorting: The automatic arrangement of data in a specific order (in this case, by date) so the most relevant information appears first.

2.4 Business Value

This feature provides essential visibility into the supply chain process. By allowing users to quickly pull filtered lists of deliveries, the business can:

– Improve Customer Service: Quickly answer customer inquiries regarding the status of their orders.

–

Enhance Operational Efficiency: Easily identify which deliveries are pending or delayed without manually searching through individual records.

- Support Data-Driven Decisions: Provide a clean, organized way to export or review delivery performance over specific periods.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/sale

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Create Sale" feature allows the system to record a new sale transaction through our API. When a request is made, the system automatically bundles the main sale details, the individual items purchased, and the payment information into a single, unified record. This ensures that all parts of a sale are captured accurately and consistently.

1.2 Step-by-Step Flow

1. Security Check: The system verifies that the user is logged in and has the necessary permissions to record sales for the specific store requested.
2. Data Validation: The system checks the incoming information to ensure it is formatted correctly and contains all required fields.
3. Transaction Processing: If the data is valid, the system begins a "transaction." This acts as an all-or-nothing process: it saves the main sale record, all individual items, and all payment details simultaneously.
4. Finalization: If everything is saved successfully, the system confirms the creation and returns the details of the new sale (including its unique ID and "draft" status). If any part of the process fails, the system cancels the entire operation to prevent incomplete or corrupted data.

1.3 Key Concepts

- Transaction: A safety mechanism that ensures all parts of a sale (the header, items, and payments) are saved together. If one part fails, the entire sale is rolled back so no partial data is left behind.
- Workflow State: A status indicator for the sale. When first created, the sale is automatically set to "draft" status.
- Authorization: A security gate that ensures only users with the correct access rights can create sales for a specific store.
- Schema Validation: A quality control step that ensures the data sent to the API matches the expected structure (e.g., ensuring prices are numbers and IDs are in the correct format).

1.4 Business Value

This feature streamlines the sales process by allowing external systems to push complete transaction data into the Lumi ERP in one go. By using a single-transaction approach, we guarantee data integrity—meaning you will never have a "sale" without its corresponding items or payment records. This reduces manual entry errors and ensures that financial reporting remains accurate and reliable.

2. Data

2.1 Overview

The "Create Sale" feature allows the system to record a new sale transaction through our API. When a request is made, the system captures the primary sale details, the specific items purchased, and the payment information in one unified action. This ensures that all parts of a sale are recorded accurately and simultaneously.

2.2 Step-by-Step Flow

1. Initiation: The system receives a request to create a new sale.
2. Primary Record Creation: A new sale record is created in the system, automatically assigned a "draft" status and a timestamp.
3. Item Logging: All individual products or items associated with the sale are recorded and linked to the primary sale.
4. Payment Logging: All payment details provided for the sale are recorded and linked to the primary sale.
5. Finalization: The system confirms that all data has been saved successfully. If any part of this process fails, the system automatically cancels the entire operation to prevent incomplete or "broken" sales records from being saved.

2.3 Key Concepts

- Atomic Transaction: A safety mechanism that ensures all parts of a sale (the record, the items, and the payments) are saved together. If one part fails, nothing is saved, keeping the data clean and consistent.
- Draft State: The initial status assigned to a new sale, indicating that it has been created but may still be subject to further processing or finalization.
- Data Integrity: The practice of ensuring that every sale is complete, with no missing items or payment information, by validating the request before it is finalized.

2.4 Business Value

This feature provides a reliable and efficient way to process sales. By using an "all-or-nothing" approach to saving data, the business avoids common issues like "orphaned" records (where a sale exists but its items or payments are missing). This creates a trustworthy foundation for financial reporting and inventory management, ensuring that every sale recorded in the system is complete and accurate.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The "Get Sale by ID" feature provides a secure way to retrieve comprehensive details for a specific sales transaction within the Lumi ERP system. By providing a unique sale identifier, authorized users can instantly access key information, including customer details, total transaction amounts, current status, and a breakdown of the individual items included in that sale.

1.2 Step-by-Step Flow

1. Request Identification: The system receives a request containing the specific ID of the sale you wish to view.
2. Security Verification: The system checks that the user is logged in and has the necessary permissions to view sales data. If the user is not logged in or lacks permission, the request is blocked.
3. Data Retrieval: The system searches the database for the sale record matching the provided ID.
4. Validation: If no sale is found with that ID, the system informs the user that the record does not exist.
5. Item Aggregation: Once the sale is located, the system gathers all individual items associated with that specific transaction.
6. Response Compilation: The system bundles the sale information (such as dates, status, and total) with the list of items into a single, organized report.
7. Delivery: The complete sale details are sent back to the user.

1.3 Key Concepts

- Authentication: The process of verifying the identity of the user to ensure they are a recognized member of the system.
- Authorization: The process of checking if a verified user has the specific permission required to view sensitive sales records.
- Sale Entity: The primary record containing high-level information about a transaction, such as the customer, total cost, and current status.
- Sale Items: The specific products or services linked to a sale, which are retrieved alongside the main record to provide a complete view of the transaction.

1.4 Business Value

This feature streamlines operations by providing a reliable, self-service method for staff to verify transaction details without manual database lookups. By enforcing strict security checks, it ensures that sensitive financial data is only accessible to authorized personnel, maintaining data integrity and compliance within the Lumi ERP environment.

2. Data

2.1 Overview

This feature provides a way to retrieve comprehensive details for a specific sale within the Lumi ERP system. By using a unique sale identifier, the system gathers both the high-level transaction information (such as the customer, total amount, and status) and the specific line items associated with that sale, presenting them together in a single, unified view.

2.2 Step-by-Step Flow

1. Request: The system receives a request to view a specific sale using its unique ID.
2. Verification: The system checks the database to see if a sale record exists for that ID.
3. Data Retrieval: If the sale is found, the system automatically fetches all related line items (the individual products and quantities) linked to that specific sale.
4. Aggregation: The system combines the main sale record and the list of items into one complete package.
5. Response: The system returns the full details to the user. If the ID does not exist or a system error occurs, the user is notified with an appropriate status message.

2.3 Key Concepts

- Sale Record: The primary document containing general information about a transaction, such as the customer involved, the total cost, and the current status of the order.
- Line Items: The individual components of a sale, detailing exactly which products were purchased, in what quantity, and at what price.
- Unique Identifier (ID): A specific code assigned to every sale that acts as a digital "fingerprint," ensuring the system retrieves the correct information every time.
- Aggregate Object: A combined set of data that brings together the main sale record and its associated line items so that the user gets all necessary information in one request.

2.4 Business Value

This feature streamlines the sales review process by eliminating the need to search for transaction details and product lists separately. By providing a single, reliable source for complete sale information, it improves operational efficiency for sales teams and ensures that customer service representatives have immediate access to accurate order history when assisting clients.

BUSINESS REQUIREMENTS DOCUMENT

PUT /api/sales/:id/{status}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a simple way to update the status of a specific sales record within the Lumi ERP system. By using this tool, authorized users or integrated systems can transition a sales record between different stages—such as moving a sale from a "Draft" state to "Complete" or "Canceled"—ensuring that the system always reflects the current progress of a transaction.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to update a specific sales record by providing the unique ID of the sale and the desired new status.
2. Validation: The system checks if the requested status is valid (must be "Draft," "Complete," or "Canceled"). If the status is unrecognized, the request is rejected.
3. Record Verification: The system searches the database to ensure a sales record with the provided ID actually exists. If it cannot be found, the system notifies the user that the record is missing.
4. Update Execution: If the ID is valid and the status is correct, the system updates the record with the new status and records the exact time the change occurred.
5. Confirmation: Upon a successful update, the system returns the updated record details to confirm the change. If an unexpected technical issue occurs during this process, the system logs the error and notifies the user that a server error has taken place.

1.3 Key Concepts

- Sales ID: A unique identifier used to pinpoint the exact sales record that needs to be modified.
- Status: The current state of a sales transaction, which helps track the lifecycle of a sale from its initial creation to its final outcome.
- Validation: A safety check performed by the system to ensure that only approved status labels are applied, preventing data errors.
- Timestamp: An automated record of exactly when the status change was processed, providing an audit trail for the sales activity.

1.4 Business Value

This feature streamlines sales operations by allowing for quick, automated status updates. By standardizing how sales records transition through their lifecycle, the business gains better visibility into active, completed, and canceled sales. This reduces manual administrative work and ensures that reporting and inventory management are always based on the most up-to-date information.

2. Data

2.1 Overview

This feature provides a reliable way to update the status of a specific sales record within the Lumi ERP system. Whether a sale is moving from a draft to completion or being canceled, this tool ensures that the status change is validated, recorded, and timestamped accurately.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to update a specific sales record with a new status.
2. Validation: The system checks if the requested status is one of the three allowed options: "Draft," "Complete," or "Canceled." If the status is not recognized, the request is rejected.
3. Record Lookup: The system searches the database to ensure the sales record associated with the provided ID actually exists. If the ID is not found, the request is rejected.
4. Update Execution: Once validated, the system updates the record with the new status and automatically records the current date and time of the change.
5. Confirmation: The system saves the changes and confirms the successful update.

2.3 Key Concepts

- Sales Status: The current state of a transaction, which can only be set to "Draft," "Complete," or "Canceled."
- Validation: A safety check performed by the system to ensure that only permitted status changes are processed, preventing data errors.
- Timestamping: The automatic recording of the exact time a change occurs, ensuring an accurate audit trail for every sales record.
- Error Handling: Built-in safeguards that provide clear feedback if a request fails (e.g., if the record doesn't exist or the status is invalid).

2.4 Business Value

This feature streamlines sales operations by providing a standardized, automated way to manage the lifecycle of a sale. By enforcing strict status rules and maintaining accurate timestamps, the business gains better visibility into sales progress, reduces manual data entry errors, and ensures that reporting on completed or canceled sales is always reliable and up-to-date.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/sales-orders

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows the system to programmatically create new sales orders within the Lumi ERP. When an external request is received, the system validates the information, ensures all referenced entities (such as customers, warehouses, and products) exist, and then saves the order as a "draft." This ensures that sales data is captured accurately and consistently before it moves through the rest of the fulfillment workflow.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the request is coming from an authorized user with a valid session.
2. Data Validation: The system checks that the request contains all required information and is formatted correctly.
3. Entity Verification: The system confirms that the customer, warehouse, salesperson, and all individual products listed in the order actually exist in the database.
4. Order Creation: If all checks pass, the system creates the main sales order record and links all individual items to that order.
5. Transaction Finalization: The system saves the entire order as a single unit. If any part of the process fails, the system cancels the entire operation to prevent incomplete or corrupted data.
6. Confirmation: Upon success, the system returns a confirmation message containing the new order details.

1.3 Key Concepts

- Draft State: All new orders are initially created in a "draft" status, allowing for review or further updates before the order is processed.
- Transactional Integrity: A "safety-first" approach where the system ensures that either the entire order and all its items are saved successfully, or nothing is saved at all, preventing partial data entry.
- Entity Validation: A verification step that ensures the order is linked to valid, existing records (like a real customer or a real product) to maintain data integrity.

1.4 Business Value

This feature enables seamless integration between the Lumi ERP and external sales channels. By automating the creation of sales orders, businesses can reduce manual data entry errors, speed up order processing times, and ensure that all sales information is immediately available for inventory and fulfillment teams to act upon.

2. Data

2.1 Overview

The "Create Sales Order" feature allows users to submit a new sales order into the Lumi ERP system. When a request is made, the system verifies that all provided information—such as the customer, warehouse, salesperson, and products—is valid and exists within the company's records. If everything is correct, the system saves the order as a "draft" and records all associated items, ensuring the entire process is completed reliably.

2.2 Step-by-Step Flow

1. Validation: The system checks the incoming request to ensure all required identifiers (customer, warehouse, salesperson, and products) are valid and currently exist in the system.
2. Error Handling: If any identifier is missing or invalid, the system rejects the request and notifies the user.
3. Data Processing: If validation passes, the system initiates a secure transaction to save the order.
4. Order Creation: The system creates the main sales order record, automatically setting its status to "draft" and recording the current date and time.
5. Item Association: The system links all individual products and their respective quantities to the newly created sales order.
6. Confirmation: Once the order and its items are successfully saved, the system confirms the creation of the order.

2.3 Key Concepts

- Draft Workflow State: The initial status assigned to a new order, indicating it has been created but is not yet finalized or processed.
- Data Integrity: The process of verifying that all references (like customer or product IDs) are accurate before saving, which prevents errors and orphaned data.
- Transaction: A safety mechanism that ensures the order and its items are saved together as a single unit; if any part of the process fails, nothing is saved, keeping the data consistent.

2.4 Business Value

This feature provides a reliable and standardized way to capture sales data. By validating information at the point of entry, it prevents data entry errors and ensures that every sales order is correctly linked to existing customers, products, and staff. The use of a "draft" state allows sales teams to initiate orders and manage them through the system workflow without prematurely finalizing them, supporting better operational control and accuracy in sales reporting.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-orders/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a secure way for the system to retrieve the full details of a specific sales order. When a user views a sales order in the Lumi ERP, this function fetches the order's core information—such as its current status and creation date—along with a list of all items included in that order. The system is designed to ensure that users can only access orders belonging to their own company, maintaining strict data privacy and security.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and identifies which company they belong to. If the user is not logged in, the request is denied.
2. Order Retrieval: The system searches for the specific sales order using the provided ID. It applies a filter to ensure the order belongs to the user's company and is a standard sales order (excluding wholesale store orders).
3. Validation: If the order cannot be found—either because it doesn't exist or because it belongs to a different company—the system returns a "Not Found" error.
4. Item Collection: Once the order is located, the system gathers all the individual line items associated with that specific order.
5. Data Delivery: The system compiles the order details and the list of items into a single report and sends it back to the user's screen.

1.3 Key Concepts

- Authentication: The process of confirming the user's identity and company affiliation to ensure they have permission to view the requested data.
- Data Scoping: A security measure that automatically filters information so that users only see records relevant to their own organization.
- Line Items: The individual products, quantities, and prices that make up a single sales order.
- Order Status: A label (such as "Draft," "Approved," or "Delivered") that tells the system which version of the order screen to display to the user.

1.4 Business Value

This feature is essential for the daily operations of the sales team. By providing a reliable and secure way to pull up order details, it allows staff to quickly check the status of a customer's request and review the specific items ordered. Because the system automatically handles security and filtering, it reduces the risk of data leaks between companies and ensures that users only interact with the information they are authorized to see.

2. Data

2.1 Overview

This feature provides a way for users to view the specific details of a sales order. When a user requests a sales order by its unique ID, the system retrieves the order information along with its associated line items (such as product names, quantities, and prices). The feature is designed to be secure, ensuring that users can only access orders belonging to their own company.

2.2 Step-by-Step Flow

1. Session Validation: The system checks if the user is logged in and has a valid company session. If the session is missing or invalid, the request is rejected.
2. Data Retrieval: The system searches for the requested sales order. It strictly filters the search to ensure the order belongs to the user's company and is a standard sales order (excluding wholesale store orders).
3. Verification: If the order is not found—either because it doesn't exist or because it belongs to a different company—the system returns a "Not Found" error.
4. Item Collection: If the order is found, the system gathers all individual line items associated with that specific order.
5. Response: The system compiles the order details (status, creation date) and the list of items into a structured format and sends it back to the user.

2.3 Key Concepts

- Multi-tenancy: A security practice that ensures data is isolated; users can only view information that belongs to their specific company.
- Sales Order Header: The primary record containing high-level information about the order, such as its current status and creation date.
- Line Items: The individual products, quantities, and prices that make up the contents of a sales order.
- Scope Filtering: A rule that automatically excludes certain types of data (in this case, wholesale store orders) from the search results to ensure the user only sees relevant business transactions.

2.4 Business Value

This feature enables the Sales Order detail page to function correctly by providing accurate, real-time data. By enforcing strict security and filtering rules, it protects sensitive company data while ensuring that sales teams can quickly access the specific order information they need to manage their workflows, such as checking order status or reviewing itemized lists.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-invoices/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve the full details of a specific sales invoice. When a user views an invoice in the Lumi ERP, this process gathers all the necessary information—such as customer details, the original sales order, and a breakdown of the items—to display the invoice accurately on the screen. It ensures that users only see invoices belonging to their own company and provides the specific data needed to manage returns and track item quantities.

1.2 Step-by-Step Flow

1. Request Verification: The system receives a request for a specific invoice ID and confirms the user is logged in and authorized to view data for their company.
2. Data Retrieval: The system searches the database for the requested invoice. If the invoice is not found or does not belong to the user's company, the system returns an error.
3. Gathering Related Details: Once the invoice is located, the system automatically pulls in supporting information, including the associated customer’s name, the original sales order number, and a list of all items included in that invoice.
4. Calculating Quantities: For every item on the invoice, the system calculates the invoiced amount, how much has already been returned, and how much remains.
5. Final Delivery: The system compiles all this information into a single, organized summary and sends it to the user's screen so the invoice details can be displayed.

1.3 Key Concepts

- Sales Invoice: The primary document representing a completed sale, containing the total amount, current status, and a list of products sold.
- Workflow State: The current stage of the invoice (e.g., pending, paid, or returned), which dictates which action buttons (like "Process Return") are available to the user.
- Quantity Tracking: A breakdown for each item that shows the original quantity sold, the quantity returned, and the remaining balance, which is essential for processing future returns.
- Company Scope: A security measure that ensures users can only access invoices that belong to their specific organization.

1.4 Business Value

This feature streamlines the sales management process by providing a "single source of truth" for invoice details. By automatically calculating remaining quantities and linking related customer and order data, it reduces manual effort for staff and minimizes errors when processing returns. Additionally, by using the workflow state to control which buttons appear, the system guides users through the correct business processes, ensuring that only valid actions are taken based on the invoice's current status.

2. Data

2.1 Overview

This feature provides a way for the system to retrieve the full details of a specific sales invoice. When a user views an invoice in the application, this process gathers all relevant information—such as customer details, the original sales order, item quantities, and the current status of the invoice—to display on the screen. It ensures that users can only access invoices that belong to their own company.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in. If not, the request is rejected.
2. Data Retrieval: The system looks up the requested invoice in the database, ensuring it matches the specific ID provided and belongs to the user's company.
3. Data Compilation: If the invoice is found, the system gathers the invoice header, associated customer and sales order information, total amounts, and a breakdown of items (including quantities invoiced, returned, and remaining).
4. Response Delivery:

* If successful, the system sends the complete invoice details to the user.

* If the invoice cannot be found, the system returns a "Not Found" error.

* If an unexpected issue occurs, the system returns a general server error.

2.3 Key Concepts

- Aggregate: A collection of related data (like customer info, order details, and line items) bundled together to provide a complete view of a single invoice.
- Workflow State: The current status of an invoice (e.g., pending, paid, or returned), which dictates which buttons and options are available to the user on the screen.
- Company Scope: A security measure that ensures users can only view data belonging to their own organization, preventing unauthorized access to other companies' records.
-

Quantity Tracking: The system tracks three specific values for each item: how many were originally invoiced, how many have been returned, and how many remain, which helps manage returns and inventory accuracy.

2.4 Business Value

This feature is essential for the daily operations of the sales team. By providing a comprehensive view of an invoice, it allows staff to quickly verify order details, check payment status, and accurately process returns. Because it automatically calculates remaining quantities, it reduces manual errors and ensures that the "New Sales Order Return" process is always populated with up-to-date, reliable data.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-invoices

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

The Sales Invoices API provides a secure way for authorized users to retrieve a list of sales invoices associated with their company. This feature allows users to search, filter, and organize invoice data, making it easier to track billing status and manage financial records directly from the system.

1.2 Step-by-Step Flow

1. Authentication: The system verifies the user's identity. If the user is not logged in or lacks permission, the request is rejected.
2. Parameter Processing: The system collects the user's search criteria (such as invoice number, customer name, or status) and pagination preferences (how many results to show and where to start).
3. Data Retrieval: The system searches the database for invoices that match the provided filters, ensuring the results are strictly limited to the user's own company.
4. Result Compilation: The system calculates the total number of matching invoices and prepares the requested page of data.
5. Response: The system returns the list of invoices along with the total count to the user.

1.3 Key Concepts

- Filtering: The ability to narrow down the list of invoices by specific criteria, such as the invoice number, the related sales order, the customer's name, or the current status (e.g., draft, paid, or cancelled).
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Authentication: A security check that ensures only verified users can access company-specific financial data.
- Scope: The system automatically restricts data access to the user's specific company, preventing unauthorized access to other organizations' information.

1.4 Business Value

This feature streamlines financial operations by providing quick, programmatic access to invoice data. By allowing users to filter by status or customer, the API helps teams efficiently monitor outstanding payments, verify billing history, and integrate invoice data with other business tools, ultimately reducing manual administrative work and improving data accuracy.

2. Data

2.1 Overview

The Sales Invoice API allows users to retrieve a list of sales invoices associated with their company. This feature is designed to help users track billing status, search for specific invoices, and manage wholesale sales orders efficiently. The system automatically ensures that users only see data belonging to their own organization, maintaining strict data security.

2.2 Step-by-Step Flow

1. Authentication Check: The system verifies the user's identity and automatically restricts the search to invoices belonging to their specific company.
2. Applying Filters: The system applies any requested search criteria, such as invoice number, specific sales order ID, customer name, or current invoice status (e.g., draft, paid, cancelled).
3. Calculating Totals: The system counts the total number of invoices that match the search criteria to help with navigation.
4. Sorting: The results are organized by the date they were created, showing the most recent invoices first.
5. Pagination: The system returns a specific "page" of results (based on the requested limit and offset) along with the total count, ensuring the application remains fast even when there are many invoices.

2.3 Key Concepts

- Company Scoping: A security measure that ensures users only access invoices linked to their own company account, without needing to manually specify a company ID.
- Filtering: The ability to narrow down the list of invoices using specific details like the customer's name or the status of the invoice.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks to improve performance and readability.
- Workflow State: The current stage of an invoice in the billing process, such as "Draft," "Approved," "Sent," "Paid," or "Cancelled."

2.4 Business Value

This feature provides a reliable way for sales and accounting teams to monitor billing activity. By allowing users to filter by specific sales orders or customer names, it reduces the time spent searching for documents. Furthermore, the built-in pagination and automated company-level security ensure that the system remains both performant and secure as the volume of sales data grows.

BUSINESS REQUIREMENTS DOCUMENT

POST /api/sales-order-returns

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature allows users to record a "Sales Order Return" within the Lumi ERP system. It enables businesses to track items being returned by customers against a specific original sales invoice. The system ensures data integrity by validating that all returned items are accounted for correctly and that the return process is linked to the appropriate warehouse and customer records.

1.2 Step-by-Step Flow

1. Validation: The system checks that the warehouse, customer, and sales invoice provided in the request exist and belong to the user's company.
2. Item Verification: The system confirms that at least one item is being returned and that the quantity for each item is greater than zero.
3. Quantity Check: The system verifies that the requested return quantity does not exceed the amount originally sold on the invoice (accounting for any items already returned).
4. Record Creation: If all checks pass, the system generates a unique return number and creates the return record in a "draft" status.
5. Transaction Finalization: The return header and all associated items are saved to the database simultaneously. If any part of this process fails, the entire operation is canceled to prevent data errors.
6. Confirmation: Upon success, the system returns the details of the newly created return record.

1.3 Key Concepts

- Sales Order Return: A formal record documenting items sent back by a customer, linked to an original invoice.
- Draft Status: The initial state of a return, allowing for review before it is finalized or processed.
- Transaction: A safety mechanism that ensures all parts of the return (the header and the individual items) are saved together; if one part fails, nothing is saved.
- Over-return Prevention: A safeguard that prevents users from returning more items than were originally purchased on the invoice.

1.4 Business Value

This feature provides a reliable audit trail for customer returns, ensuring that inventory levels are accurately managed and that returns are always tied to valid sales invoices. By automating the validation of quantities and ownership, the system reduces manual errors and prevents fraudulent or incorrect return entries, ultimately improving inventory accuracy and customer service efficiency.

2. Data

2.1 Overview

This feature allows users to record a sales order return within the Lumi ERP system. When a customer returns items, this process creates a formal record linked to the original sales invoice, ensuring that the return is tracked accurately against the correct warehouse, customer, and invoice details.

2.2 Step-by-Step Flow

1. Validation: The system checks that the warehouse, customer, and sales invoice exist and belong to the user's company. It also verifies that the invoice belongs to the specified customer.
2. Quantity Verification: The system ensures that the requested return quantity is greater than zero and does not exceed the amount originally sold (accounting for any items already returned).
3. Return Number Generation: The system automatically generates a unique identification number for the return.
4. Record Creation: The system creates the return header (containing general information) and the individual return items in a single, unified action.
5. Status Assignment: The new return is saved with an initial status of "Draft."
6. Confirmation: Upon successful creation, the system returns the details of the newly created return record.

2.3 Key Concepts

- Atomicity: A safety mechanism that ensures the entire return record (the header and all individual items) is saved successfully as one unit. If any part of the process fails, nothing is saved, preventing incomplete or corrupted data.
- Returnable Quantity: The remaining balance of an item from an original invoice that is eligible to be returned. The system prevents users from returning more items than were originally purchased.
- Draft Status: The initial state of a new return, indicating that the record has been created but is not yet finalized or processed.
- Ownership Validation: A security check to ensure that the warehouse, customer, and invoice selected for the return are authorized for the user's specific company.

2.4 Business Value

This feature provides a reliable and controlled way to manage product returns, which is essential for maintaining accurate inventory levels and financial records. By automating the validation of return quantities against original invoices, the system prevents errors and over-crediting, ensuring that the company’s sales data remains consistent and trustworthy.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-deliveries/:id

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve the full details of a specific sales delivery. By providing a unique delivery ID, the system will return the status of the delivery, the date it was created, and a list of all items included in that shipment. This information is essential for populating the Sales Delivery detail page, allowing users to view the current progress and contents of their orders.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in. If the user is not authenticated, the request is denied.
2. Data Retrieval: Using the provided delivery ID, the system searches for the specific delivery record, ensuring it belongs to the user's company.
3. Validation: If no delivery record is found for that ID within the company's account, the system reports that the record does not exist.
4. Item Collection: Once the delivery record is located, the system gathers all individual line items associated with that specific delivery.
5. Display: The system compiles the delivery information (status, date, and items) and sends it back to the user to be displayed on the screen.

1.3 Key Concepts

- Sales Delivery: A record representing the shipment of goods, including its current status (e.g., draft or delivered) and the date it was created.
- Line Items: The specific products and quantities associated with a single sales delivery.
- Company Scope: A security measure that ensures users can only view delivery records that belong to their own organization.
- Unique Identifier (ID): A specific reference code used to pinpoint one exact delivery record among all others in the system.

1.4 Business Value

This feature enables transparency in the sales process. By allowing users to pull up detailed delivery information on demand, staff can quickly verify order contents and track the status of shipments. This reduces manual lookup time and ensures that the information displayed on the user interface is always accurate and tied directly to the company's official records.

2. Data

2.1 Overview

This feature provides a way for the Lumi ERP system to retrieve the full details of a specific sales delivery. When a user views a delivery record, the system fetches both the high-level delivery information (such as the status and creation date) and the specific list of items included in that delivery. The system automatically ensures that users can only access delivery records that belong to their own company.

2.2 Step-by-Step Flow

1. Verification: The system confirms the user is logged in and identifies which company they belong to.
2. Header Retrieval: The system searches for the requested sales delivery record. It verifies that the record exists and strictly confirms it belongs to the user's company.
3. Item Retrieval: If the delivery record is found, the system then gathers all individual line items associated with that specific delivery.
4. Data Assembly: The system combines the delivery header information and the list of items into a single, complete package to be displayed on the screen.
5. Response: The combined information is sent to the user's interface. If the record cannot be found or does not belong to the company, the system returns an error message.

2.3 Key Concepts

- Sales Delivery Header: The primary record containing general information about the delivery, such as its current status (e.g., draft or delivered) and when it was created.
- Line Items: The specific products and quantities associated with a particular delivery.
- Company Scope: A security measure that ensures users can only view data belonging to their own organization, preventing unauthorized access to other companies' information.
- Aggregate: The complete set of data, combining the header and the line items, provided to the user in one request.

2.4 Business Value

This feature enables a seamless user experience for managing sales operations. By providing a single, reliable source for delivery details, it allows the interface to accurately display the status of an order and its contents. Furthermore, the built-in security checks ensure data privacy by guaranteeing that sensitive sales information remains accessible only to the appropriate company personnel.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/sales-deliveries/:id/{status}

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a streamlined way to update the status of a sales delivery within the Lumi ERP system. It allows users to mark a delivery as either "delivered" or "voided." This action is designed to be simple and direct, acting as a final confirmation step to ensure that delivery records accurately reflect their current progress in the supply chain.

1.2 Step-by-Step Flow

1. Validation: The system checks that the requested status is either "delivered" or "voided." If an incorrect status is provided, the request is rejected.
2. Security Lock: The system locks the specific delivery record to ensure that no other processes can modify it while the update is in progress.
3. Verification: The system confirms the delivery exists and verifies that it is currently in a "draft" state. If the delivery has already been processed or is missing, the request is rejected.
4. Status Update: The system updates the delivery status to the requested value.
5. Automatic Order Completion: If the status is set to "delivered," the system automatically updates the associated sales order to "completed" and marks it as closed. If the status is "voided," the sales order remains unchanged.
6. Confirmation: The system returns a success message confirming the new status of the delivery.

1.3 Key Concepts

- Workflow State: The current stage of a document (e.g., "draft" or "completed"). This ensures that users only perform actions that are appropriate for the current phase of the delivery.
- Database Transaction: A safety mechanism that ensures all related updates (like updating both the delivery and the parent sales order) happen together. If any part of the process fails, the entire action is canceled to prevent data errors.
- Locking: A protective measure that prevents two users from trying to change the same record at the exact same time, which helps maintain data integrity.

1.4 Business Value

- Operational Efficiency: Automates the closing of sales orders once a delivery is marked as "delivered," reducing the manual administrative burden on staff.
-

Data Accuracy: By restricting status changes to "draft" items only, the system prevents accidental or unauthorized changes to deliveries that have already been finalized.

- Consistency: Ensures that the status of a sales order always stays in sync with its corresponding delivery, providing a reliable view of business operations for reporting and inventory management.

2. Data

2.1 Overview

This feature provides a reliable way to update the status of a sales delivery within the Lumi ERP system. It allows authorized users to mark a delivery as either "delivered" or "voided." The system ensures that these updates are processed safely, preventing conflicting changes and automatically updating the status of the parent sales order when a delivery is successfully completed.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to update a specific delivery to a new status ("delivered" or "voided").
2. Validation: The system checks that the requested status is valid and that the delivery record exists.
3. Locking: The system locks the specific delivery record to ensure no other processes can modify it while the update is in progress.
4. State Check: The system verifies that the delivery is currently in a "draft" state. If it is not, the update is rejected to prevent accidental changes to finalized deliveries.
5. Status Update: The delivery status is updated to the new value.
6. Parent Order Sync (Conditional): If the status is set to "delivered," the system automatically checks the parent sales order. It recalculates the order's overall status and determines if the order should be marked as "closed" based on the completion of all associated deliveries.
7. Completion: The system confirms the update is successful and returns the updated delivery information.

2.3 Key Concepts

- Workflow State: The current stage of a delivery or order (e.g., "draft," "delivered").
- Transaction: A safety mechanism that ensures all related updates (like updating a delivery and its parent order) happen together successfully or not at all, preventing data inconsistencies.
- Locking: A protective measure that prevents two users from trying to change the same record at the exact same time.
-

Draft State: A required starting point for a delivery; the system only allows status changes if the delivery is currently in this initial state.

2.4 Business Value

- Data Integrity: By using automated status synchronization, the system ensures that sales orders always accurately reflect the progress of their deliveries without manual intervention.
- Error Prevention: The "draft" state requirement prevents users from accidentally modifying or voiding deliveries that have already been processed.
- Operational Efficiency: Automating the "closed" status for sales orders reduces the administrative burden on staff, ensuring that completed orders are correctly categorized in the system immediately upon delivery.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-quotations

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

The Sales Quotations API allows users to retrieve a list of sales quotations generated for their company. This feature is designed to help sales teams track, search, and manage their outgoing quotes efficiently. The system automatically ensures that users only see data belonging to their own organization, maintaining strict data privacy.

1.2 Step-by-Step Flow

1. Authentication Check: The system identifies the user and automatically restricts the search to only include quotations associated with that user's company.
2. Applying Filters: The system processes any optional search criteria provided by the user, such as:

* Document Number: Finds quotes starting with a specific sequence of characters.

* Sales Order ID: Filters for quotes linked to a specific sales order.

* Customer Name: Searches for quotes containing a specific customer name.

* Status: Filters by the current stage of the quote (e.g., draft, sent, accepted).

3. Sorting and Organization: The system organizes the results by the date they were created, showing the most recent quotations first.
4. Pagination: To keep the data manageable, the system returns results in smaller "pages" (defined by a limit and offset), providing a total count of all matching records so the user knows how much data is available.
5. Data Delivery: The system returns the requested list of quotations, including key details like the document number, customer name, status, and relevant timestamps.

1.3 Key Concepts

- Data Scoping: A security measure that ensures users can only access information relevant to their specific company.
- Filtering: The ability to narrow down a large list of records to find specific items based on criteria like customer name or document status.
- Pagination: A method of breaking a large list of results into smaller, easier-to-read chunks to improve performance and usability.
- Workflow State: The current stage of a quotation in the sales process (e.g., whether it is still a draft, has been sent to a customer, or has been converted into an order).

1.4 Business Value

This feature provides sales teams with a reliable way to monitor the status of their quotations. By allowing users to quickly filter and search through their records, it reduces the time spent manually looking for documents. Furthermore, the built-in pagination and automated company-level security ensure that the system remains fast and secure, even as the volume of sales data grows.

2. Data

2.1 Overview

The Sales Quotations API allows users to retrieve a list of sales quotations created for their company. This feature is designed to help sales teams track, filter, and manage their outgoing price quotes efficiently. The system automatically ensures that users only see data belonging to their own organization, maintaining strict data privacy.

2.2 Step-by-Step Flow

1. Authentication: The system identifies the user's company automatically based on their login session.
2. Filtering: The system applies any requested filters to narrow down the results. Users can search by:
   - Document Number: Finds quotes starting with a specific sequence.
   - Sales Order ID: Shows quotes linked to a specific sales order.
   - Customer Name: Finds quotes containing a specific customer name.
   - Status: Filters by the current stage of the quote (e.g., draft, sent, accepted).
3. Counting: The system calculates the total number of matching records to assist with navigation.
4. Sorting: The results are automatically organized by the date they were created, showing the most recent quotes first.
5. Pagination: The system returns a specific "page" of results based on the requested limit and offset, ensuring the application remains fast even with a large volume of data.
6. Delivery: The final list of quotations and the total count are sent back to the user.

2.3 Key Concepts

- Pagination: A method of breaking a large list of data into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down a large list of records to find specific items based on criteria like customer name or document status.
- Scope: The security mechanism that ensures a user can only access data associated with their specific company, preventing unauthorized access to other organizations' information.
-

Workflow State: The current status of a quotation (e.g., "Sent" or "Accepted"), which helps teams understand where a deal stands in the sales cycle.

2.4 Business Value

This feature provides sales teams with a reliable way to monitor their pipeline. By enabling quick searches and filtered views, users can spend less time hunting for documents and more time managing customer relationships. Furthermore, the automated sorting and pagination ensure that the system remains responsive and easy to navigate, even as the company's sales history grows over time.

Version 1.0	**Date** September 22, 2026	**Status** Draft	**Classification** Internal

BUSINESS REQUIREMENTS DOCUMENT

GET /api/sales-order-returns/:id

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature provides the data necessary to display the "Sales Order Return" detail page in the Lumi ERP system. When a user selects a specific return, this tool retrieves all relevant information—such as the return status, the warehouse involved, and a detailed list of the products being returned—ensuring the user sees the most up-to-date information, including current stock levels for those items.

1.2 Step-by-Step Flow

1. Authentication Check: The system verifies that the user is logged in and identifies which company they belong to, ensuring they can only view returns associated with their own organization.
2. Locate Return Record: The system searches for the specific return record requested by the user. If the record does not exist or belongs to a different company, the system reports that it cannot be found.
3. Retrieve Line Items: Once the return record is found, the system gathers all individual product items associated with that specific return.
4. Enrich Data: For every product in the return, the system looks up its official name and checks the current inventory level specifically at the warehouse designated to receive the return.
5. Final Compilation: The system bundles the return header information (such as the current status and creation date) with the enriched list of products and sends this complete package to the screen for display.

1.3 Key Concepts

- Workflow State: The current status of the return (e.g., Draft, Received, Approved, or Cancelled), which determines how the page is displayed to the user.
- Receiving Warehouse: The specific storage location where the returned items are expected to arrive; this is used to calculate the accurate stock levels for the return.
- Enriched Line Items: A list of returned products that includes not just the quantity, but also the product name and the current stock availability at the receiving warehouse.
- Company Scope: A security measure that ensures users only have access to data belonging to their own company.

1.4 Business Value

This feature streamlines the returns process by providing warehouse and customer service staff with a "single source of truth" for any given return. By automatically displaying the current stock levels alongside the returned items, staff can make faster, more informed decisions about inventory management and return processing without needing to navigate to separate inventory screens.

2. Data

2.1 Overview

This feature provides the data necessary to power the "Sales Order Return" detail page in the Lumi ERP system. When a user views a specific return, this API retrieves the full record—including the header information and the list of items being returned—and automatically enriches it with real-time inventory data for the warehouse receiving those items.

2.2 Step-by-Step Flow

1. Request Validation: The system verifies the user's identity and ensures the request is scoped to their specific company to maintain data security.
2. Record Retrieval: The system searches for the specific return record using the provided ID. If the record does not exist or belongs to a different company, the system returns a "Not Found" error.
3. Inventory Lookup: For every item listed in the return, the system identifies the receiving warehouse and checks the current stock level for that specific product.
4. Data Enrichment: The system combines the original return details with the real-time stock levels found in the previous step.
5. Response: The complete, enriched data package is sent to the user interface, allowing the page to display the return status and the current stock levels for each item.

2.3 Key Concepts

- Sales Order Return: A document tracking items being sent back by a customer, including its current status (e.g., draft, received, approved, or cancelled).
- Line Items: The individual products included within a single return request.
- Data Enrichment: The process of taking the basic return information and adding extra, real-time context (in this case, current warehouse stock) so the user has all the information they need in one view.
- Company Scoping: A security measure that ensures users can only access return data that belongs to their own organization.

2.4 Business Value

- Improved Decision Making: By displaying the current stock level directly on the return page, warehouse staff can immediately see if the returned items will cause overstock or if they are needed to fulfill other pending orders.
-

Operational Efficiency: Users no longer need to navigate to separate inventory screens to check stock levels; the information is presented contextually within the return workflow.

- Data Integrity: By automatically linking the return to the specific receiving warehouse, the system ensures that stock data is accurate and relevant to the location where the return is being processed.

BUSINESS REQUIREMENTS DOCUMENT

PATCH /api/sales-invoices/:id/workflow

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Logic

1.1 Overview

This feature allows users to manage the lifecycle of a sales invoice by moving it through different stages (such as approving, sending, or cancelling). By using this update tool, the system ensures that invoices only move through logical, pre-defined paths, preventing errors like sending an invoice that hasn't been approved yet.

1.2 Step-by-Step Flow

1. Locate the Invoice: The system searches for the specific invoice using the unique ID provided. If the invoice cannot be found, the process stops and notifies the user.
2. Validate the Action: The system checks the invoice's current status (e.g., "Draft") against the requested action (e.g., "Approve"). If the action is not allowed for the current status, the system rejects the request.
3. Update and Record: If the action is valid, the system updates the invoice to its new status and records the change in the system history for auditing purposes.
4. Confirm Success: Once the update is complete, the system returns the updated invoice details so the user can see the current status and timestamp.

1.3 Key Concepts

- Workflow State: The current stage of an invoice in its lifecycle, such as "Draft," "Approved," or "Sent."
- Action: The specific command requested by the user to change the invoice's status, such as "Approve" or "Cancel."
- Transition Rules: The built-in logic that dictates which actions are permitted based on the current status of the invoice.
- Audit Trail: A secure record created automatically whenever an invoice status changes, ensuring there is a history of who moved the invoice and when.

1.4 Business Value

This feature enforces consistency and accuracy in your sales process. By restricting status changes to only those that make business sense, you reduce the risk of human error—such as accidentally skipping an approval step. Additionally, the automated logging provides a clear history of invoice activity, which simplifies reporting and improves accountability across your sales operations.

2. Data

2.1 Overview

This feature provides a controlled way to manage the lifecycle of a sales invoice within the Lumi ERP system. By using this update tool, users can move an invoice through various stages—such as approving a draft or sending an invoice—while ensuring that only logical, permitted transitions occur. This prevents errors, such as accidentally skipping a required approval step.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to perform a specific action on a sales invoice (e.g., "approve" a draft).
2. Verification: The system retrieves the current status of the invoice to confirm it exists.
3. Validation: The system checks the requested action against the invoice's current status. If the action is not allowed (for example, trying to "approve" an invoice that is already "sent"), the request is rejected.
4. State Update: If the action is valid, the system updates the invoice to its new status.
5. Audit Logging: The system automatically records the change in a history log, noting the new status and the time the change occurred.
6. Confirmation: The system returns the updated invoice details to the user, allowing the interface to refresh with the latest information.

2.3 Key Concepts

- Workflow State: The current stage of an invoice in its lifecycle (e.g., Draft, Approved, Sent, or Cancelled).
- Transition: The process of moving an invoice from one state to another (e.g., moving from "Draft" to "Approved").
- Validation Rules: Built-in logic that ensures an invoice can only move to a logical next step, preventing invalid or out-of-order status changes.
- Audit Trail: A permanent record of all status changes, which provides transparency and accountability for how an invoice reached its current state.

2.4 Business Value

- Process Integrity: By enforcing strict transition rules, the system ensures that company financial processes are followed consistently, reducing the risk of human error.
- Improved Compliance: The automatic audit logging provides a clear history of invoice activity, which is essential for financial reporting and internal audits.
- Operational Efficiency: Users receive immediate feedback if an action is invalid, and the system automatically handles the transition logic, saving time and reducing the need for manual status management.

BUSINESS REQUIREMENTS DOCUMENT

Sales Ecommerce JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a structured way to retrieve and display a list of ecommerce sales within the Lumi ERP system. It allows users to search, filter, and view sales data specifically originating from online channels, ensuring that the information is organized, paginated, and easy to navigate.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request for a list of ecommerce sales, which may include specific search filters (such as customer name, store, or date range) and pagination settings.
2. Data Retrieval: The system queries the sales database, specifically isolating records marked as "ecommerce" and excluding any that have been voided.
3. Information Enrichment: During the search, the system links each sale to its corresponding store name to provide a complete view of the transaction.
4. Dynamic Filtering: The system applies the user's search criteria. Notably, if a user filters by "completed" status, the system automatically uses the completion date for the search; otherwise, it uses the creation date.
5. Formatting: The retrieved data is organized into a standardized format, ensuring fields like customer details, vehicle information, and transaction totals are clearly presented.
6. Response Delivery: The final list is returned to the user, accompanied by pagination details (total count, current page, and limit) to help manage large volumes of data.

1.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve system performance and user experience.
- Filtering: The ability to narrow down the list of sales based on specific criteria, such as date, store location, or customer name.
- Data Enrichment: The process of combining information from different sources (in this case, linking a sale to a store name) to provide a more meaningful report.
- Workflow State: The current status of a sale (e.g., pending, completed), which dictates how the system processes and displays the record.

1.4 Business Value

This feature centralizes ecommerce sales data, allowing staff to efficiently track online orders. By providing robust filtering and pagination, it enables users to quickly locate specific transactions, monitor store performance, and manage customer inquiries without being overwhelmed by large datasets. This ensures that the sales team has accurate, real-time visibility into online revenue and order fulfillment status.

Sales Store JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. LOGIC

1.1 Overview

The Sales Store feature provides a structured way for the Lumi ERP system to manage and retrieve point-of-sale (POS) transaction data. It allows the system to list sales, view detailed information for a specific transaction, and record new sales. The feature ensures that data is consistently organized, filtered, and paginated, making it easier for store staff to track sales performance and manage customer records.

1.2 Step-by-Step Flow

1. Listing Sales: When viewing the sales list, the system automatically filters for POS-originated transactions and excludes any voided sales. Users can further refine this list using optional filters like date ranges, store location, salesperson, or customer name. The system returns a paginated list of sales, including key details like the store name and total amount.
2. Viewing Sale Details: When a user selects a specific sale, the system retrieves the full record. This includes the primary sale information, a breakdown of all items purchased (such as products and quantities), and the payment methods used for that transaction.
3. Creating a New Sale: When a new sale is processed, the system captures the core transaction data, the list of items sold, and the payment details. These are saved together as a single, unified record to ensure the financial and inventory data remains accurate.

1.3 Key Concepts

- Pagination: A method of breaking large lists of sales into smaller, manageable pages to improve system performance and readability.
- Workflow State: The current status of a sale (e.g., draft, pending, completed, or voided), which determines how the sale is displayed and processed.
- Source: A label identifying where the sale originated (e.g., POS, ecommerce, or other), ensuring that store-specific reports only include relevant data.
- Denormalization: The practice of including descriptive information (like "Store Name" or "Customer Name") directly within the sale record, so the system doesn't have to look up those details from other areas every time a sale is viewed.
- Transaction: A safety feature that ensures all parts of a new sale—the main record, the items, and the payments—are saved successfully together; if any part fails, the entire sale is rolled back to prevent incomplete data.

1.4 Business Value

- Operational Efficiency: By providing a dedicated view for POS sales with built-in filtering and search, staff can quickly locate specific transactions without manual sorting.
- Data Integrity: The use of standardized schemas ensures that every sale record is complete and consistent, reducing errors in financial reporting and inventory tracking.
- Improved Customer Service: By linking customer and vehicle information directly to sales, staff can easily access history and provide more personalized service at the point of sale.
- Scalability: The structured approach to handling sales data allows the business to grow across multiple store locations while maintaining a unified and reliable reporting process.

2. DATA

2.1 Overview

This feature establishes a standardized "blueprint" (JSON Schema) for how the Lumi ERP system handles sales data. By defining exactly what information is required and how it should be formatted, we ensure that the system consistently records and displays sales information across the platform. This covers both viewing a list of store sales and creating new sales records.

2.2 Step-by-Step Flow

1. Data Retrieval (Viewing Sales): When a user views the "Store Sales" list, the system pulls data from the central sales database. It combines this with store information to provide a clear, readable list of transactions.
2. Standardized Formatting: The system applies a strict structure to this data, ensuring that every sale includes essential details like the document number, date, customer name, vehicle registration, status, and total amount.
3. Pagination: To keep the interface fast and responsive, the system organizes the sales list into manageable pages, providing the total count of records to help the user navigate through the history.
4. Data Submission (Creating Sales): When a new sale is created, the system validates the incoming information against the required blueprint. This ensures that the sale, its individual items, and the payment details are all captured correctly before being saved to the database.

2.3 Key Concepts

- JSON Schema: A standardized set of rules that defines the "shape" of data, ensuring that information sent to or received from the system is complete and correctly formatted.
- Sale Entity: The core record representing a transaction, containing high-level details like the store, salesperson, and total amount.

- Sale Items: The individual products or services included within a single sale, tracking quantities, prices, and taxes for each line item.
- Sale Payments: The financial breakdown of how a sale was settled, including the payment method (e.g., cash, card) and the specific amount paid.
- Workflow State: The current status of a sale (e.g., draft, pending, completed, or voided), which determines how the sale is displayed and handled in the system.

2.4 Business Value

- Data Integrity: By enforcing a strict structure, we prevent errors and missing information, ensuring that financial and operational reports are always accurate.
- System Reliability: Standardized schemas allow different parts of the software to "talk" to each other reliably, reducing bugs and unexpected behavior when updating or viewing sales.
- Improved User Experience: Consistent data formatting ensures that the sales list is always easy to read, searchable, and navigable, allowing staff to quickly find the information they need.
- Scalability: A clear blueprint makes it easier for the development team to add new features or integrations in the future without disrupting existing sales processes.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order JSON schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. DATA

1.1 Overview

The Sales Order JSON schema defines the structure for how sales order information is organized and retrieved within the Lumi ERP system. This feature ensures that when a user views a specific sales order, the system provides a consistent, comprehensive, and accurate summary of the order, including header information (such as customer and warehouse details) and a detailed list of the items purchased.

1.2 Step-by-Step Flow

1. Request: The system receives a request to view a specific sales order by its unique identifier.
2. Validation: The system verifies that the requested sales order belongs to the authenticated user's company to ensure data security.
3. Data Retrieval: The system fetches the main order details (the "header") from the database, including information about the customer, the warehouse, and the salesperson.
4. Item Assembly: The system retrieves all individual line items associated with that specific sales order.
5. Response Construction: The system combines the header information and the list of items into a single, structured response that follows the defined JSON schema, ensuring all required fields (like totals, tax, and status) are present and correctly formatted.

1.3 Key Concepts

- Sales Order Header: The top-level information for an order, such as the customer name, warehouse location, total amounts, and the current status of the order (e.g., draft, approved, or delivered).
- Line Items: The individual products or services included in a sales order, detailing the quantity ordered, quantity delivered, unit price, and any discounts applied.
- JSON Schema: A standardized "blueprint" that defines the required format for data, ensuring that the information sent to the user interface is always consistent and predictable.
- Data Scoping: A security measure that ensures users can only access sales orders that belong to their specific company.

1.4 Business Value

- Data Consistency: By using a strict schema, the system ensures that every sales order is displayed in the same way, reducing errors and making it easier for the front-end application to process the data.
- Improved Accuracy: The structured approach to retrieving order details and line items ensures that financial totals (subtotal, tax, and total) are calculated and presented reliably.
- Enhanced Security: The built-in scoping mechanism prevents unauthorized access to sales data, ensuring that company information remains private and secure.

- Operational Efficiency: By providing a complete view of the order—including warehouse and customer details—in a single request, the system allows staff to quickly review and manage sales orders without needing to look up information in multiple places.

BUSINESS REQUIREMENTS DOCUMENT

Sales Delivery JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a standardized way for the system to organize and share information about sales deliveries. By defining a clear structure (a "schema") for this data, we ensure that the application can consistently display delivery details—such as customer information, warehouse locations, and specific product items—across different parts of the software. This setup supports both searching for a list of deliveries and viewing the comprehensive details of a single delivery.

1.2 Step-by-Step Flow

1. Filtering and Searching: When you need to find specific deliveries, the system allows you to search by reference codes, warehouse location, or the current status of the delivery (e.g., draft, confirmed, or delivered).
2. Retrieving Delivery Details: When you select a specific delivery to view, the system fetches the "header" information, which includes the primary details like the customer, warehouse, and overall financial totals.
3. Fetching Line Items: Simultaneously, the system pulls the list of individual products associated with that specific delivery.
4. Assembling the View: The system combines the header information and the list of products into a single, organized package to be displayed on your screen.
5. Security Check: Throughout this process, the system verifies that the requested delivery belongs to your company, ensuring that sensitive data remains private and secure.

1.3 Key Concepts

- Sales Delivery: A record representing the shipment of goods to a customer, containing both high-level summary information and a list of specific items included in the shipment.
- Workflow State: The current stage of a delivery in its lifecycle, such as "draft" (in progress), "confirmed" (ready for shipment), "delivered" (completed), or "voided" (cancelled).
- Schema: A blueprint that defines exactly what information is included in a record, ensuring that every delivery is formatted the same way every time it is accessed.
- Multi-tenant Security: A protective measure that ensures users can only view data belonging to their own company, preventing unauthorized access to other organizations' records.

1.4 Business Value

- Data Consistency: By using a standardized format, all parts of the ERP system "speak the same language," reducing errors when moving data between different screens or reports.
- Improved Searchability: The ability to filter by status and reference codes allows staff to quickly locate specific shipments, saving time during daily operations.

- Enhanced Security: The built-in company-level filtering ensures that sensitive sales and inventory data is strictly siloed, maintaining compliance and data privacy.
- Operational Clarity: Providing a complete view of a delivery—including both the summary and the specific items—gives staff the full context they need to manage orders effectively.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order Status Transition JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature manages the lifecycle of a Sales Order by allowing authorized users to transition an order's status to either "approved" or "cancelled." It ensures that these changes follow strict business rules, preventing invalid status updates and protecting data integrity during concurrent operations.

1.2 Step-by-Step Flow

1. Request Initiation: A user submits a request to change the status of a specific Sales Order to either "approved" or "cancelled."
2. Data Locking: The system locks the specific Sales Order record in the database. This prevents other users from modifying the same order at the exact same time, which avoids data conflicts.
3. Validation: The system checks the current status of the order against the requested change:

* An order can only be approved if it is currently in "draft" status.

* An order can only be cancelled if it is currently in "draft" or "approved" status.

4. Status Update: If the transition is valid, the system updates the order's status, records the user who made the change, and updates the timestamp. If the order is approved, the system also records the exact time of approval.
5. Finalization: The transaction is completed, and the updated order details are returned to the user. If any step fails (e.g., the order is not found or the transition is invalid), the entire process is cancelled to ensure no partial or incorrect data is saved.

1.3 Key Concepts

- Transaction: A safety mechanism that ensures a series of database operations either all succeed together or all fail together, preventing partial data updates.
- State Machine: A set of rules that defines the allowed "path" an order can take (e.g., you cannot jump from "cancelled" back to "approved").
- Locking: A method used to temporarily restrict access to a specific record so that only one process can modify it at a time, preventing "race conditions" where two users might try to change the status simultaneously.
- Draft: The initial state of a new Sales Order before it has been formally approved or cancelled.

1.4 Business Value

- Data Integrity: By enforcing strict transition rules, the system prevents orders from entering illogical states (e.g., approving an order that has already been cancelled).
- Operational Reliability: The use of database locks ensures that multiple users cannot accidentally overwrite each other's changes, providing a consistent and reliable experience for the sales team.

- Auditability: Every status change is tracked with the user's ID and a timestamp, providing a clear history of who approved or cancelled an order and when.

BUSINESS REQUIREMENTS DOCUMENT

Sales Invoice JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Sales Invoice feature in the Lumi ERP system provides a structured way to generate and manage customer invoices based on completed sales deliveries. It ensures that financial records are accurately linked to the goods delivered, maintains a clear workflow for invoice approval and processing, and provides a comprehensive view of invoice details, including payment status and line-item breakdowns.

1.2 Step-by-Step Flow

1. Invoice Creation: When a user initiates a new invoice, the system selects one or more "delivered" sales deliveries. It automatically pulls the relevant customer, product, and pricing information from these deliveries to populate the invoice.
2. Data Consolidation: The system calculates the financial totals (subtotal, tax, and final amount due) based on the items copied from the deliveries.
3. Linking Records: Once the invoice is created, the system updates the original sales deliveries to link them to the new invoice, ensuring that each delivery is accounted for and preventing duplicate invoicing.
4. Workflow Management: Newly created invoices start in a "draft" state. Users can then move the invoice through various stages—such as "approved" or "sent"—to reflect the current status of the billing process.
5. Retrieval and Review: Users can view a detailed summary of any invoice, which includes the header information, payment history, and a list of all items included in that specific invoice.

1.3 Key Concepts

- Sales Invoice: A formal document representing a request for payment for goods or services delivered to a customer.
- Workflow State: The current status of an invoice (e.g., draft, approved, sent, paid, or cancelled), which dictates what actions can be performed next.
- Sales Delivery: The source record for an invoice; it represents the physical or digital fulfillment of a customer's order.
- Transaction: A safety mechanism that ensures all parts of the invoice creation process (creating the invoice, adding items, and updating delivery records) happen together successfully or not at all, preventing data errors.
- Primary Key: A unique identifier for each invoice or item, ensuring that every record in the system can be accurately tracked and retrieved.

1.4 Business Value

-

Accuracy and Consistency: By automatically pulling data from existing sales deliveries, the system eliminates manual data entry errors and ensures that the invoice perfectly matches the goods actually delivered.

- Operational Efficiency: The automated workflow and linking of deliveries to invoices save time for the finance team and provide clear visibility into which deliveries have been billed and which are still pending.
- Improved Financial Control: The structured status tracking (workflow states) allows businesses to maintain better control over their billing cycle, ensuring that invoices are approved before being sent to customers and accurately marked as paid upon receipt.

BUSINESS REQUIREMENTS DOCUMENT

Sales Quotation JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a structured way to retrieve a list of Sales Quotations within the Lumi ERP system. It allows users to view, search, and filter their company's quotations, ensuring that the information is organized, easy to navigate, and secure by restricting access to company-specific data.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to view the list of sales quotations. It automatically identifies the user's company to ensure they only see relevant records.
2. Applying Filters: The system checks for any user-provided criteria, such as a specific document number, customer name, sales order association, or current status (e.g., "draft" or "sent").
3. Data Retrieval: The system queries the database to find all matching quotations. During this process, it links the quotation to the user who last updated it, ensuring the "Updated By" name is displayed correctly.
4. Sorting and Pagination: The results are sorted based on the user's preference (e.g., by date or document number) and broken into manageable pages to ensure the application remains fast and responsive.
5. Response Delivery: The system returns the final list of quotations along with a summary of the total count, allowing the user interface to display the data and pagination controls accurately.

1.3 Key Concepts

- Pagination: A method of breaking a large list of records into smaller, manageable chunks (pages) to improve performance and readability.
- Filtering: The ability to narrow down a large list of quotations based on specific criteria like status, customer, or document number.
- Workflow State: The current stage of a quotation in its lifecycle, such as "draft," "sent," "accepted," or "converted."
- Data Security: The system automatically scopes all data requests to the authenticated company, preventing users from accessing information belonging to other organizations.
- Denormalization: Storing certain information (like the customer's name) directly with the quotation record to make searching and displaying the list faster.

1.4 Business Value

This feature empowers sales teams to efficiently manage their pipeline by providing a clear, searchable view of all active and historical quotations. By enabling quick filtering and sorting, users can easily track the status of their documents, identify which quotations are ready for follow-up, and see which have successfully converted into sales orders. This visibility helps reduce administrative overhead and improves the speed of the sales cycle.

BUSINESS REQUIREMENTS DOCUMENT

Sales Order List - Company Sales Orders Filter

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Order Filter feature provides a centralized control panel for users to quickly locate specific sales orders within the Lumi ERP system. By offering a variety of search criteria, users can narrow down large lists of orders to find exactly what they need without manually scrolling through records.

1.2 Step-by-Step Flow

1. Input Data: The user enters or selects criteria in one or more filter fields, such as the document number, PO number, date range, warehouse, customer, salesperson, or order status.
2. Initiate Search: The user clicks the "Search" button to trigger the filtering process.
3. Clean Request: The system automatically ignores any empty or blank fields, ensuring only the active criteria are sent to the database.
4. Reset Pagination: The system automatically resets the view to the first page of results (starting at the beginning of the list) to ensure the user sees the most relevant data for their new search.
5. Retrieve Data: The system sends the request to the server, which returns the specific list of sales orders matching the provided criteria.
6. Display Results: The filtered list is updated and presented to the user.

1.3 Key Concepts

- Filter Criteria: The specific data points (like date ranges or status) used to narrow down the search results.
- Active Filtering: The system's ability to ignore empty fields, ensuring that only relevant search parameters are processed.
- Pagination Reset: A standard behavior that returns the user to the first page of results whenever a new search is performed, preventing confusion when the number of results changes.
- Order Status: A category used to track the lifecycle of an order (e.g., Draft, Confirmed, or Shipped).

1.4 Business Value

This feature significantly improves operational efficiency for sales and warehouse teams. By allowing users to instantly filter by specific attributes like customer name, warehouse location, or order status, the system reduces the time spent searching for information. This leads to faster customer service responses, better inventory visibility, and a more streamlined workflow for managing the sales order lifecycle.

2. Logic

2.1 Overview

The Sales Order List filter feature allows users to quickly locate specific sales records within the Lumi ERP system. By providing a set of search criteria, users can narrow down the list of orders to find exactly what they need without scrolling through the entire database. The system is designed to be flexible, meaning it only applies filters for the information you provide, ignoring any empty fields.

2.2 Step-by-Step Flow

1. Input Selection: The user enters search criteria into one or more available fields, such as the document number, customer name, date range, warehouse location, salesperson, or order status.
2. Triggering the Search: Upon clicking the "Search" button, the system collects all active filter values.
3. Data Retrieval: The system sends a request to the database, including only the fields that have been filled out. It automatically sets a default view of 20 results to ensure the page loads quickly.
4. Processing Results: The system receives the matching sales orders and organizes them into a standardized format.
5. Display: The filtered list of sales orders is presented to the user, showing key details like the order date, status, and total amount.

2.3 Key Concepts

- Filter Criteria: The specific data points (like dates or customer names) used to narrow down the search results.
- Dynamic Querying: A method where the system only searches based on the fields you have filled in, rather than requiring every field to be completed.
- Pagination: A feature that limits the number of results shown at once (defaulting to 20) to keep the interface clean and performant.
- Data Mapping: The process of taking raw information from the system and organizing it into a clear, readable list for the user.

2.4 Business Value

This feature significantly improves operational efficiency by reducing the time staff spend searching for specific sales orders. By allowing users to filter by common business identifiers—such as purchase order numbers or specific date ranges—the system minimizes manual effort and reduces the likelihood of errors. This streamlined access to information supports faster customer service responses and more accurate order tracking.

3. Data

3.1 Overview

The Sales Order List filter feature allows users to quickly locate specific sales records within the Lumi ERP system. By providing a set of flexible search criteria, users can narrow down large volumes of data to find exactly what they need, whether they are searching by document numbers, dates, specific customers, or the status of an order.

3.2 Step-by-Step Flow

1. Input Selection: The user enters search criteria into one or more available filter fields (such as date ranges, customer names, or order status).
2. Request Submission: When the user clicks the "Search" button, the system collects only the fields that contain information and sends them as a request to the database.
3. Data Filtering: The system processes the request by applying the provided filters to the sales order records. It intelligently matches partial information (like a partial document number) and looks up related details (like matching a customer name to their unique ID).
4. Pagination: To ensure the system remains fast and easy to read, the results are returned in manageable chunks (defaulting to 20 records at a time).
5. Display: The filtered list of sales orders is returned and presented to the user.

3.3 Key Concepts

- Dynamic Filtering: The system only searches based on the fields you have filled out; if a field is left blank, it is ignored, allowing for highly customizable searches.
- Partial Matching: For fields like document numbers or names, the system can find results even if you only provide a portion of the information.
- Pagination: A method of breaking large lists of data into smaller pages to improve performance and make the information easier to navigate.
- Relational Lookup: The ability to search for orders by human-friendly names (like a customer or salesperson's name) rather than requiring you to know their internal system ID numbers.

3.4 Business Value

This feature significantly improves operational efficiency for sales and warehouse teams. By reducing the time spent manually scrolling through long lists, staff can respond to customer inquiries faster, track order statuses more accurately, and maintain better oversight of company sales activity. The flexible search options ensure that users can find information using the terminology they are already familiar with, reducing training time and errors.

BUSINESS REQUIREMENTS DOCUMENT

Add Customer Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Customer Modal" is a pop-up feature designed for the Lumi ERP Sales module. It allows sales staff to quickly register a new customer and their associated vehicle details directly within the sales process. The feature includes built-in safeguards to ensure essential information is captured correctly before the record is saved.

1.2 Step-by-Step Flow

1. Open Modal: The user triggers the "Add New Customer" pop-up from the sales screen.
2. Data Entry: The user fills out three main sections:

* Basic Info: Captures personal details like name, contact information, and store assignment.

* Address Details: A hierarchical selection process where choosing a province, regency, or district automatically updates the available options for the next level, ensuring accurate location data.
* Vehicle Details: Captures specific vehicle information. Selecting a vehicle model automatically populates the vehicle category.

3. Real-Time Validation: As the user types, the system checks for required fields (such as Name, Phone, Store, and Vehicle details). If a required field is left empty, the system immediately flags it.
4. Submission: Once all required fields are valid, the "Save" button becomes active.
5. Processing: Upon clicking "Save," the system sends the data to the database. If successful, the modal closes and the sales view refreshes; if an error occurs, the user is notified so they can correct the information.

1.3 Key Concepts

- Real-time Validation: A feature that checks for missing information as you type, preventing errors before you attempt to save.
- Hierarchical Address Selection: A smart form behavior where selecting a broader location (like a province) narrows down the choices for more specific locations (like a district), making data entry faster and more accurate.
- Derived Data: Information that is automatically filled in by the system based on other selections (e.g., the vehicle category is automatically determined once the vehicle model is chosen).
- Form State: The system’s internal tracking of whether the form is currently being submitted or if it contains errors, which controls whether the "Save" button is clickable.

1.4 Business Value

- Efficiency: Sales staff can add new customers on the fly without leaving the sales screen, reducing administrative friction.
-

Data Integrity: By enforcing required fields and using hierarchical dropdowns for addresses, the system ensures that customer records are complete and accurate from the start.

- Reduced Errors: Automated validation and derived fields minimize manual data entry mistakes, leading to cleaner customer and vehicle databases.

BUSINESS REQUIREMENTS DOCUMENT

Barcode Display

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Barcode Display feature allows the Lumi ERP system to generate and visualize barcodes based on specific label formats. It ensures that any barcode entered into the system is correctly formatted and compatible with the physical label templates used in your warehouse or retail operations.

1.2 Step-by-Step Flow

1. Input Validation: When a user enters a barcode, the system immediately checks it against three rules: it cannot be empty, it must contain only letters and numbers, and it must be between 8 and 20 characters long.
2. Error Handling: If the input does not meet these rules, the system displays a clear error message to the user, preventing invalid data from being processed.
3. Template Selection: Once the barcode is validated, the system identifies the chosen label template (such as Avery or continuous roll formats).
4. Rendering: The system applies the barcode data to the selected visual template, ensuring the final output matches the physical layout of your labels.

1.3 Key Concepts

- Barcode Validation: A built-in safety check that ensures all barcode data is consistent, readable, and follows standard length and character requirements.
- Template Mapping: The ability of the system to automatically adjust the visual layout of a barcode to fit different physical label sizes and types.
- Alphanumeric: A requirement that the barcode must consist only of letters and numbers, excluding special symbols or punctuation to ensure compatibility with scanners.

1.4 Business Value

This feature streamlines the labeling process by removing guesswork and manual formatting. By enforcing strict validation rules, it prevents printing errors that could lead to unreadable barcodes. Furthermore, by supporting multiple label templates, the system provides the flexibility to switch between different label stocks without needing to reconfigure the software, saving time and reducing operational friction.

BUSINESS REQUIREMENTS DOCUMENT

Tax JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

The Tax JSON Schema feature provides a structured way for the Lumi ERP system to manage, retrieve, and display tax-related records. It allows users to view detailed tax information—including associated suppliers, warehouses, and line-item breakdowns—through a flexible search and filtering system. This ensures that financial data is organized, easily accessible for reporting, and ready for use in dropdown menus or comprehensive list views.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to either fetch a simple list of active tax options (for dropdown menus) or a detailed, paginated list of tax records.
2. Filtering: If a detailed list is requested, the system applies any provided filters, such as status (active/inactive), specific date ranges (based on creation or update dates), or a specific tax ID.
3. Pagination: The system calculates the total number of records matching the filters and divides them into pages to ensure the application remains fast and responsive.
4. Data Retrieval: The system fetches the core tax records from the database.
5. Data Enrichment: For each tax record found, the system automatically gathers related information, such as supplier details, warehouse locations, user information, journal entries, and individual tax line items.
6. Summary Calculation: The system calculates totals (such as subtotal, tax amount, and grand total) based on the retrieved line items.
7. Response Delivery: The final, enriched data set is returned to the user interface, including metadata about the total number of records and pages available.

1.3 Key Concepts

- Pagination: A method of breaking large amounts of data into smaller, manageable chunks (pages) to improve system performance and user experience.
- Filtering: The ability to narrow down search results based on specific criteria like dates or status, helping users find exactly what they need.
- Data Enrichment: The process of automatically pulling in related information (like supplier or warehouse names) so that a single tax record provides a complete, "all-in-one" view of the transaction.
- Tax Line Items: Individual components of a tax record that detail specific products, quantities, prices, and discounts, which are then used to calculate the final tax summary.
- Workflow State: A status indicator that helps distinguish between active tax records and those that are no longer in use.

1.4 Business Value

This feature centralizes tax data management, reducing the time spent manually cross-referencing information across different parts of the ERP. By providing automated summaries and flexible filtering, it enables finance teams to generate accurate reports quickly and ensures that tax information is consistently available for both high-level overviews and detailed audits.

BUSINESS REQUIREMENTS DOCUMENT

Sales Invoice List

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Invoice List feature provides a centralized dashboard for finance teams to view, search, and manage all sales invoices within the Lumi ERP system. It allows users to quickly locate specific invoices using various filters, organize the data by clicking on column headers, and navigate directly to detailed records for further action.

1.2 Step-by-Step Flow

1. Initial Load: When you open the Invoices page, the system automatically fetches the list of invoices using default sorting and pagination settings.
2. Filtering: You can narrow down the list by entering criteria into the search bar (such as Invoice Number, Purchase Order, Sales Order, or Customer Name) or by selecting specific dates and statuses.
3. Applying Search: Once your filters are set, clicking the "Search" button refreshes the list, resets the view to the first page, and displays only the records that match your criteria.
4. Sorting: You can click on any column header (e.g., Invoice Date, Total, or Status) to sort the list. Clicking once sorts the data in ascending order; clicking again reverses it to descending order.
5. Pagination: If there are many invoices, you can use the pagination controls at the bottom of the table to move between pages.
6. Navigation: You can click on specific items within a row—such as the Invoice Number, Sales Order, or Customer Name—to be taken directly to the corresponding details page for that record.

1.3 Key Concepts

- Filters: Tools that allow you to refine the list of invoices based on specific data points like dates, status, or reference numbers.
- Pagination: A method of breaking a large list of records into smaller, manageable pages to improve performance and readability.
- Sorting: The ability to reorder the list based on a specific column, making it easier to find the most recent or highest-value invoices.
- Mapping: The process where the system takes raw data from the database and presents it in a user-friendly table format.

1.4 Business Value

This feature streamlines the finance workflow by reducing the time spent searching for documentation. By providing a responsive, searchable, and sortable list, users can quickly reconcile accounts, track invoice statuses, and

access related customer or order information without navigating through multiple screens. This improves overall operational efficiency and ensures that financial data is always easily accessible.

2. Logic

2.1 Overview

The Sales Invoice List feature provides a centralized view for users to browse, search, and manage sales invoices within the Lumi ERP system. It is designed to handle large volumes of data efficiently by using pagination and sorting, ensuring that users can quickly locate specific financial documents without performance delays.

2.2 Step-by-Step Flow

1. Initial Load: When the user opens the Sales Invoice page, the system automatically fetches the first page of invoices using default settings (sorted by issue date).
2. Data Retrieval: The system requests the invoice data from the database, applying any active filters, sorting preferences, or pagination settings.
3. Data Mapping: The raw information retrieved from the system is translated into a user-friendly table format, ensuring key details like invoice numbers, customer names, dates, and totals are clearly displayed.
4. Search Execution: When a user enters a search term and clicks the search button, the system clears the current view, resets the pagination to the first page, and fetches a new list of results matching the search criteria.
5. Display: The final processed data is rendered in the table, accompanied by pagination controls that allow the user to navigate through the full list of invoices.

2.3 Key Concepts

- Pagination: A method of breaking a large list of invoices into smaller, manageable pages (defaulting to 20 items per page) to improve loading speed and readability.
- Search Filtering: The ability to narrow down the invoice list by entering specific keywords, which triggers a fresh request to the system to find relevant matches.
- Sorting: The organization of invoices based on specific criteria, such as the issue date, to help users prioritize or find recent entries.
- Data Mapping: The process of taking raw system data and converting it into the specific columns and labels shown in the user interface.

2.4 Business Value

This feature streamlines the financial workflow by providing a responsive and intuitive interface for invoice management. By enabling quick searches and organized browsing, it reduces the time administrative staff spend locating documents, minimizes manual errors, and ensures that users always have access to the most up-to-date status of their sales invoices.

3. Data

3.1 Overview

The Sales Invoice List feature provides a centralized view for users to browse, search, and manage all sales invoices within the Lumi ERP system. This feature is designed to help finance teams quickly locate specific billing records by offering flexible search options, organized sorting, and a paginated view to ensure the interface remains fast and easy to navigate even as the number of invoices grows.

3.2 Step-by-Step Flow

1. Request Initiation: When you open the Sales Invoice page or perform a search, the system collects your criteria, such as search keywords, your preferred page number, and sorting preferences.
2. Filtering: The system scans the invoice database for matches based on the invoice number or the customer's name.
3. Sorting: The results are organized based on your chosen criteria (e.g., by date or amount). If no preference is selected, the system defaults to showing the most recently issued invoices first.
4. Pagination: To keep the list manageable, the system divides the invoices into smaller groups (pages). It calculates which specific set of records to display based on the page number you are viewing.
5. Data Delivery: The system compiles the requested list of invoices along with the total count of records found, ensuring you have a clear overview of your search results.

3.3 Key Concepts

- Search Filter: A tool that allows you to find specific invoices by typing in either a unique invoice number or a customer's name.
- Pagination: A method of breaking a large list of invoices into smaller, readable pages to improve performance and user experience.
- Sorting: The ability to arrange the list in a specific order, such as by date or total amount, to help you prioritize your work.
- Default View: The initial state of the page, which automatically displays the most recent invoices in a standard, easy-to-read format.

3.4 Business Value

This feature streamlines financial operations by reducing the time spent manually searching for billing documents. By providing a responsive and searchable list, finance staff can quickly verify invoice statuses, track customer billing history, and maintain accurate records. The inclusion of pagination and sorting ensures that the system remains efficient and user-friendly, regardless of the volume of sales data being managed.

BUSINESS REQUIREMENTS DOCUMENT

Add Sales Invoice /sales_invoices/new?sales_order_id=1147551

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Add Sales Invoice" feature allows users to create a new invoice directly from an existing sales delivery. When a user navigates to this page, the system automatically pulls in the relevant order and customer information, ensuring accuracy and saving time by eliminating the need for manual data entry.

1.2 Step-by-Step Flow

1. Security Verification: Upon loading the page, the system checks if the user is currently logged in. If the session has expired or the user is not authenticated, they are automatically redirected to the login screen.
2. Data Retrieval: The system identifies the specific sales delivery associated with the request. It then fetches the corresponding sales order reference code and customer name from the database.
3. Form Pre-filling: The retrieved information is automatically populated into the "Sales Order" and "For Customer" fields on the invoice form.
4. Data Integrity: These pre-filled fields are set to "read-only" (disabled). This ensures that the invoice remains strictly linked to the original delivery details, preventing accidental changes during the invoicing process.

1.3 Key Concepts

- Pre-filling: The automated process of populating form fields with existing data to reduce manual effort and human error.
- Read-only Fields: Form inputs that display information but cannot be edited by the user, ensuring that critical data remains consistent with the source record.
- Authentication Check: A security measure that ensures only logged-in users can access financial data and create invoices.

1.4 Business Value

- Efficiency: By automatically pulling in customer and order details, staff can generate invoices much faster.
- Accuracy: Eliminating manual entry for these fields prevents typos and data mismatches between the delivery record and the final invoice.
- Process Consistency: By locking the reference fields, the system enforces a standardized workflow where invoices are always tied directly to their originating sales delivery, simplifying financial auditing and tracking.

2. Logic

2.1 Overview

The "Add Sales Invoice" feature streamlines the billing process by automatically pulling information from an existing sales delivery. When a user navigates to the invoice creation page, the system verifies their identity and immediately populates key fields—such as the sales order reference and customer name—based on the delivery record provided. This eliminates the need for manual data entry, ensuring accuracy and saving time during the invoicing workflow.

2.2 Step-by-Step Flow

1. Security Check: When the page loads, the system verifies that the user is currently logged in. If the session is invalid or expired, the user is automatically redirected to the login screen.
2. Data Retrieval: Once authenticated, the system uses the specific delivery ID from the web address to look up the relevant sales delivery details.
3. Form Pre-filling: The system extracts the sales order reference code and the customer's name from the delivery record.
4. UI Update: These details are automatically inserted into the "Sales Order" and "For Customer" fields on the invoice form, allowing the user to proceed with the invoice creation immediately.

2.3 Key Concepts

- Authentication: A security step that ensures only logged-in users can access the invoicing tools.
- Pre-filling: The process of automatically populating form fields with existing data to reduce manual effort and prevent typing errors.
- Sales Delivery: The source record that contains the necessary information (like customer identity and order references) required to generate an accurate invoice.

2.4 Business Value

- Increased Efficiency: By automating the entry of customer and order details, staff can generate invoices significantly faster.
- Improved Data Accuracy: Pre-filling information directly from the source record minimizes the risk of human error, such as selecting the wrong customer or entering an incorrect order reference.
- Seamless Workflow: The feature creates a smooth transition from the delivery stage to the billing stage, providing a more intuitive experience for finance team members.

BUSINESS REQUIREMENTS DOCUMENT

Sales Invoice Detail - Company /sales_invoices/[record_id]#details-tab-content

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Sales Invoice Detail feature provides a comprehensive view of an individual customer invoice within the Lumi ERP system. It allows finance users to review invoice data, track the current status of the invoice through its lifecycle, and perform necessary actions to move the invoice forward (such as approving or sending it to the customer).

1.2 Step-by-Step Flow

1. Loading: When you open a specific invoice, the system automatically retrieves all relevant data, including customer details, line items, and financial totals.
2. Review: You can view the invoice's current status (e.g., Draft, Approved, Sent, or Paid) and examine the breakdown of costs, including subtotals, discounts, taxes, and the final amount due.
3. Workflow Management: Depending on the current status, the system displays specific action buttons:

* Draft: You can Approve, Send, or Cancel the invoice.

* Approved: You can Send the invoice to the customer or Reset it back to a draft if changes are needed.

4. Update: When you click an action button, the system processes the request and immediately refreshes the screen to show the updated status and any new available actions.

1.3 Key Concepts

- Workflow State: The current stage of the invoice in the billing process (Draft, Approved, Sent, Paid, or Cancelled). This determines which buttons are available to the user.
- Financial Breakdown: A clear summary of the invoice math, showing how the final "Amount Due" is calculated after applying discounts, credit notes, and taxes.
- Action Buttons: Context-aware controls that allow users to transition an invoice from one state to another without needing to navigate to different pages.
- Details Grid: A static display of essential invoice information, such as dates, customer billing address, and tax identification numbers.

1.4 Business Value

This feature centralizes the invoice management process, reducing the time spent navigating between different screens. By providing a clear, status-driven interface, it minimizes errors in the billing workflow and ensures that finance teams can quickly identify the next required step for any invoice, ultimately helping to accelerate the payment collection cycle.

2. Logic

2.1 Overview

The Sales Invoice Detail feature provides a comprehensive view of an individual invoice within the Lumi ERP system. It allows users to view all financial data associated with an invoice—such as billing details, line items, and payment status—and manage the invoice's lifecycle through a guided workflow (e.g., approving, sending, or cancelling an invoice).

2.2 Step-by-Step Flow

1. Page Load: When a user opens a specific sales invoice, the system automatically retrieves all relevant invoice data, including financial totals, customer information, and the current status.
2. Data Display: The system maps the retrieved information into the "Invoice Details" tab, organizing it into clear sections for general details, financial amounts, payment status, and individual line items.
3. Header Adaptation: The invoice header automatically updates its appearance based on the current status (e.g., "Draft," "Approved," "Sent," "Paid," or "Cancelled") to ensure the user always knows the current state of the document.
4. Workflow Interaction: Depending on the current status, the user is presented with relevant action buttons (such as "Approve" or "Reset"). Clicking an action triggers an update to the invoice's status.
5. Automatic Refresh: Once an action is performed, the system immediately refreshes the page data, updating the header, the available action buttons, and the financial values to reflect the new status.

2.3 Key Concepts

- Workflow State: The current stage of an invoice in its lifecycle, which dictates what actions a user can take and how the invoice is displayed.
- Invoice Mapping: The process of taking raw financial data and organizing it into user-friendly categories like "Amounts," "Payments," and "Invoice Items."
- Action Buttons: Context-aware controls that appear or disappear based on the invoice's current status to prevent invalid operations (e.g., you cannot "Approve" an invoice that is already "Paid").

2.4 Business Value

This feature streamlines the finance team's operations by providing a single, reliable source of truth for invoice status. By automating the transition between states and ensuring the interface always reflects the most current data, the system reduces manual errors, improves visibility into payment timelines, and ensures that users only perform valid actions at the right time.

3. Data

3.1 Overview

The Sales Invoice Detail feature provides a comprehensive view of an individual invoice within the Lumi ERP system. It allows users to see all relevant financial data, customer information, and line-item details in one place. Additionally, the feature includes a dynamic workflow system that updates the invoice status (e.g., from Draft to Approved or Sent) and adjusts the available action buttons based on the current state of the invoice.

3.2 Step-by-Step Flow

1. Data Retrieval: When a user opens a specific sales invoice page, the system automatically fetches all relevant invoice details, including customer information, financial totals, and individual product line items.
2. Display Mapping: The system organizes this data into three clear sections:

* Header: Displays the invoice reference code and the current status (e.g., Draft, Approved, Paid).

* Details & Amounts: Shows billing addresses, dates, tax information, and a breakdown of costs (subtotals, discounts, taxes, and final totals).

* Items: Lists every product included in the invoice with its specific pricing and quantity.

3. Workflow Interaction: Depending on the invoice's current status, the system presents relevant action buttons (such as "Approve," "Send," or "Cancel").
4. Status Update: When a user clicks an action button, the system updates the invoice status.
5. Automatic Refresh: Upon a successful update, the page automatically refreshes to show the new status, update the header display, and adjust the available action buttons to match the new state.

3.3 Key Concepts

- Workflow State: The current lifecycle stage of an invoice (e.g., Draft, Approved, Sent, Paid, or Cancelled), which dictates what actions a user can perform next.
- Header Component: A dynamic UI element that changes its appearance and available options based on the invoice's current workflow state.
- Line Items: The individual products or services listed on an invoice, including their specific quantities, prices, and any applied discounts.
- Financial Summary: The calculated breakdown of the invoice, including subtotals, tax, credit notes, and the final amount due versus the amount already paid.

3.4 Business Value

This feature centralizes all critical invoice information, reducing the need for users to navigate between different screens to verify billing or product details. By automating the workflow status and providing context-aware action buttons, the system minimizes manual errors and ensures that users only perform valid actions (e.g., preventing an invoice from being "Approved" if it has already been "Cancelled"). This creates a more efficient, reliable, and transparent billing process for the finance team.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - Details Card (Extension Franchise Customer)

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Franchise Customer Details Card is a read-only component designed for the Lumi ERP system. Its purpose is to provide a clear, organized view of essential information for franchise customers. The card is structured into three distinct sections to ensure that users can quickly locate specific data points regarding the customer, their primary contact person, and the assigned salesperson.

1.2 Step-by-Step Flow

1. Header Display: The card displays a "Details" header to identify the information block.
2. Customer Identity Section: The system presents core business information, including the customer code, name, region, address, national ID (KTP), contact details (phone/email), internal notes, and bank information.
3. Contact Person Section: The system displays specific details for the customer's point of contact, including their full name, professional contact information, location details (country/region), and their role within the organization (position and department).
4. Salesperson Section: The system displays the assigned salesperson's information, split into two specific fields: the salesperson's name and their unique identification number.

1.3 Key Concepts

- Read-Only: All information displayed is for viewing purposes only; users cannot edit or modify these fields directly through this component.
- Customer Identity: A collection of foundational data that defines the franchise customer within the ERP system.
- Contact Person: Specific professional details for the individual acting as the primary liaison for the franchise.
- Salesperson: The internal staff member associated with the account, identified by both name and ID for clarity.

1.4 Business Value

This feature improves operational efficiency by providing a centralized, easy-to-read summary of franchise customer data. By organizing information into logical categories, it reduces the time staff spend searching for critical details, minimizes errors during customer interactions, and ensures that all team members have consistent access to the same accurate information.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - Group Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Group card is a dedicated section on the Customer Detail page designed to provide immediate visibility into which group a customer belongs to. This component acts as a clear, read-only reference point, ensuring that users can quickly identify the organizational or categorical affiliation of a customer without needing to navigate through multiple screens.

1.2 Step-by-Step Flow

1. The system identifies the specific customer being viewed.
2. The application retrieves the group information associated with that customer.
3. The system checks if a valid group name exists for the customer.
4. If a group name is found, it is displayed clearly on the card.
5. If no group is assigned or the information is missing, the card displays a "No group assigned" placeholder to ensure the user knows the field is empty rather than broken.

1.3 Key Concepts

- Read-only field: A display-only element that prevents users from accidentally modifying the customer's group assignment directly from this view.
- Placeholder state: A user-friendly label that appears when data is unavailable, providing clarity that the field is intentionally blank.
- Customer Group: A classification or category used to organize customers within the system.

1.4 Business Value

This feature improves operational efficiency by centralizing essential customer identity information. By providing a dedicated, easy-to-read card for group affiliation, support and sales teams can quickly understand a customer's context, enabling more personalized service and accurate reporting without the need for manual data lookups.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - Settings Card (Extension Franchise Customer)

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Settings" card is a component within the Customer Detail page of the Lumi ERP system. It provides a centralized, read-only view of specific configuration settings for franchisee customers. This card ensures that users can quickly reference important business flags, accounting codes, and credit terms associated with a customer without the ability to modify them directly from this view.

1.2 Step-by-Step Flow

1. Display Header: The card displays a "Settings" header to categorize the information.
2. Show Business Flags: The system displays whether the customer is flagged as a "Franchise Store Owner" or a "Wholesale Customer."
3. Show Accounting Details: The system lists the specific accounting codes assigned to the customer, including Sales Tax, AR Invoice, Credit Note, Down Payment, Deposit, and Price Difference accounts.
4. Show Credit Terms: The system displays the customer's financial limits, specifically the Credit Term (in days), Credit Limit (in Rupiah), and Overdue Limit (in days).
5. Read-Only Enforcement: All information presented is pulled directly from the customer's existing records and is displayed in a read-only format to maintain data integrity.

1.3 Key Concepts

- Read-Only: A display state where information is visible for reference but cannot be edited or changed by the user.
- Franchise/Wholesale Flags: Boolean indicators that define the business relationship type of the customer.
- Accounting Accounts: Specific ledger codes used to categorize financial transactions (such as taxes or invoices) for that customer.
- Credit Terms and Limits: Financial parameters that define the customer's payment schedule and the maximum amount of credit they are permitted to hold.

1.4 Business Value

This feature provides transparency and quick access to critical customer configuration data. By surfacing these settings directly on the Customer Detail page, account managers and finance teams can verify a customer's status and credit parameters instantly, reducing the need to navigate to separate accounting modules. The read-only nature of the component ensures that sensitive financial and business settings remain consistent and protected from accidental changes.

1. Frontend

1.1 Overview

The Prices Card is a dedicated section on the Customer Detail page within the Lumi ERP system. Its primary purpose is to provide a clear, at-a-glance view of the specific pricing configuration assigned to a customer. This ensures that anyone viewing a customer's profile can quickly identify which pricing rules or lists apply to them without needing to navigate away from the page.

1.2 Step-by-Step Flow

1. Data Retrieval: When you open a customer's profile, the system automatically requests the relevant pricing information associated with that specific customer.
2. Loading State: While the system is gathering this information, a temporary loading indicator is displayed to let you know the data is being retrieved.
3. Display: Once the data is ready, the system displays the "Prices" section header, marked with a price icon for easy identification.
4. Information Presentation: The system shows the name of the assigned "Pricelist" (such as "Default Wholesale Price") as a read-only field. If no specific pricelist is assigned, the system will indicate that the information is not available.
5. Error Handling: If the system encounters an issue while trying to fetch the pricing data, it will display a clear message notifying you that the information could not be loaded.

1.3 Key Concepts

- Pricelist: A predefined set of pricing rules or rates assigned to a customer, which determines the costs applied to their orders.
- Read-only Field: A piece of information that is displayed for reference purposes only and cannot be edited directly within this specific view.
- Loading State: A visual placeholder that appears while the system is communicating with the database to ensure you know the page is still working.

1.4 Business Value

This feature improves operational efficiency by centralizing critical financial information. By providing immediate visibility into a customer's assigned pricelist, sales and support staff can:

* Reduce Errors: Ensure the correct pricing is applied to orders by verifying the customer's status instantly.

* Save Time: Eliminate the need to search through multiple screens or external documents to confirm pricing agreements.

* Enhance Transparency: Provide consistent information across the team, ensuring everyone is aligned on the pricing terms for each specific customer.

Customer Detail Page - Changes Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The "Customer Changes" card is a read-only information panel located on the Customer Detail page. Its purpose is to provide full transparency regarding the history and origin of a customer record. By displaying key metadata, it allows users to quickly verify when a record was created or modified, who performed those actions, and where the information originated.

1.2 Step-by-Step Flow

1. The system retrieves the customer record data from the database.
2. The "Created At" field displays the exact date and time the customer profile was first established.
3. The "Updated At" field displays the date and time of the most recent modification to the profile.
4. The "Created By" field identifies the specific user or system account that initially created the record.
5. The "Updated By" field identifies the user or system account responsible for the most recent change.
6. The "Source" field displays the origin or platform from which the customer data was last updated.

1.3 Key Concepts

- Audit Trail: A chronological record that provides documentary evidence of the sequence of activities that have affected a specific customer record.
- Read-Only: A status indicating that the information is for viewing purposes only and cannot be edited or altered by the user through this component.
- Metadata: Descriptive data that provides context about the customer record, such as timestamps and user identifiers, rather than the customer's personal information itself.

1.4 Business Value

This feature enhances data governance and accountability within the Lumi ERP. By providing a clear audit trail, team members can easily track the lifecycle of a customer record, troubleshoot data discrepancies, and maintain confidence in the accuracy of the information. Because the fields are strictly read-only, the integrity of the historical data is protected from accidental changes.

Customer Detail Page - Tax Information Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Tax Information Card is a dedicated section within the Customer Detail page designed to provide quick, read-only access to a customer's essential tax identification numbers. This component ensures that staff can easily verify a customer's tax status without needing to navigate away from the main customer profile.

1.2 Step-by-Step Flow

1. The system identifies the specific customer being viewed.
2. The page initiates a request to retrieve the customer's profile data.
3. While the data is being retrieved, a loading indicator is displayed to show that the system is working.
4. Once the data is ready, the Tax Information Card populates three specific fields: NPWP, NITKU, and NPPKP.
5. Each field is displayed alongside an information icon that provides a brief explanation of the tax term when hovered over or clicked.

1.3 Key Concepts

- NPWP: The Taxpayer Identification Number (Nomor Pokok Wajib Pajak) used for tax administration.
- NITKU: The Identity Number for a Place of Business Activity (Nomor Identitas Tempat Kegiatan Usaha), used to identify specific business locations.
- NPPKP: The Taxable Entrepreneur Confirmation Number (Nomor Pengukuhan Pengusaha Kena Pajak), which identifies businesses registered to collect value-added tax.
- Read-only: A display format where information can be viewed but not modified directly within this specific card.

1.4 Business Value

This feature centralizes critical compliance data, reducing the time staff spend searching for tax documentation. By providing clear labels and helpful tooltips for complex tax identifiers, the system minimizes errors during data verification and ensures that customer records remain accurate and easy to audit.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - Data Mapping Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Data Mapping card is a new component on the Customer Detail page within the Lumi ERP system. Its primary purpose is to provide a clear, at-a-glance view of how a specific customer is categorized or assigned within our internal records. Currently, this section focuses on identifying the specific staff member responsible for the account.

1.2 Step-by-Step Flow

1. Data Retrieval: When you open a customer's profile, the system automatically requests the relevant account details from our database.
2. Loading State: While the system gathers this information, a brief loading message is displayed to ensure you know the data is being retrieved.
3. Display: Once the data is ready, the "Data Mapping" section appears on the page, marked by a visual icon for easy identification.
4. Information Presentation: The system displays the name of the assigned Salesperson. If no salesperson has been assigned to that customer, the system will clearly indicate that the field is "Unassigned."
5. Read-Only Access: The salesperson information is presented as a read-only field, meaning it is intended for viewing purposes only and cannot be edited directly from this specific card.

1.3 Key Concepts

- Data Mapping: A dedicated section of the customer profile that organizes key administrative or organizational details about the account.
- Read-Only: A display format where information is visible for reference but cannot be modified by the user in that specific view.
- Unassigned: A default status shown when the system finds no specific salesperson linked to the customer record.

1.4 Business Value

This feature improves operational transparency by ensuring that any team member viewing a customer profile can immediately identify who is responsible for that account. By centralizing this information in a dedicated "Data Mapping" section, we reduce the time spent searching for account ownership details, leading to faster internal communication and better customer service coordination.

Customer Detail Page - Detail Menu for Wholesale and Franchisee

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Customer Detail Menu is a navigation component designed for Wholesale and Franchisee customer profiles within the Lumi ERP system. It provides a consistent sidebar that allows users to quickly switch between different information categories—such as billing, products, and history—without leaving the customer's profile page.

1.2 Step-by-Step Flow

1. Initialization: When a user opens a customer profile, the system identifies the current page and automatically highlights the corresponding menu item.
2. User Interaction: The user selects a category from the navigation list (e.g., "Addresses" or "History").
3. State Update: The system updates the visual "active" state of the menu to show the user which section they are currently viewing.
4. Navigation: The system instantly routes the user to the specific detail page associated with the selected menu item.

1.3 Key Concepts

- Active State: A visual indicator (such as highlighting) that tells the user which section of the customer profile they are currently viewing.
- Routing: The mechanism that ensures clicking a menu item takes the user to the correct, relevant page within the ERP.
- Navigation Menu: A centralized list of links that acts as the primary way to move between different data views for a specific customer.

1.4 Business Value

- Improved Efficiency: Users can navigate between complex customer data points (like billing and product history) in a single click, reducing the time spent searching for information.
- Consistent User Experience: By standardizing the navigation across all Wholesale and Franchisee profiles, the system ensures that staff can easily find the information they need, regardless of which customer they are managing.
- Reduced Errors: Clear visual feedback on the "active" section helps prevent users from accidentally entering data into the wrong category.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Menu

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Detail Menu is a navigation component designed to help users easily switch between different categories of information for a specific retail customer. It acts as a central hub, allowing staff to quickly access key areas such as contact details, vehicle history, and purchase records without leaving the customer's profile page.

1.2 Step-by-Step Flow

1. Initial Load: When a user opens a customer profile, the "Customer" tab is selected by default.
2. User Selection: The user clicks on one of the available menu items (Customer, Address, Vehicles, Purchases, or Returns).
3. State Update: The system highlights the selected tab to provide visual feedback that it is now the active section.
4. Navigation: The system automatically updates the main view to display the specific information requested by the user.
5. Synchronization: If the user navigates via the browser or other links, the menu automatically detects the current page and ensures the correct tab remains highlighted.

1.3 Key Concepts

- Active Tab State: A visual indicator that shows the user which section of the customer profile they are currently viewing.
- Navigation Routing: The underlying logic that maps each menu button to its specific data page, ensuring the correct information loads instantly.
- Default State: The starting point of the menu, which ensures the user is always presented with the primary customer information upon arrival.

1.4 Business Value

- Improved Efficiency: Staff can navigate complex customer profiles with fewer clicks, reducing the time spent searching for specific data.
- Enhanced User Experience: By providing a consistent and intuitive navigation structure, the system reduces training time and minimizes user error.
- Data Clarity: Organizing information into distinct, accessible categories ensures that retail staff can focus on the relevant customer details needed for their current task.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - SAP Reporting Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The SAP Reporting Card is a new component on the Customer Detail page designed to provide quick, read-only visibility into a customer's financial reporting attributes. This feature pulls specific data directly from our SAP system, ensuring that account managers and finance teams can easily reference key organizational codes without needing to navigate away from the customer's profile.

1.2 Step-by-Step Flow

1. Data Retrieval: When you open a customer's detail page, the system automatically requests the relevant SAP reporting information for that specific customer.
2. Loading State: While the information is being retrieved from the SAP system, a brief loading message is displayed to indicate that the data is being fetched.
3. Data Display: Once retrieved, the system populates the card with the Assignment, Cost Center, and Profit Center details.
4. Read-Only Access: The information is presented in a clear, static format. These fields cannot be edited within this view, ensuring the integrity of the data synced from SAP. If no data is available for a specific field, the system will display "N/A."

1.3 Key Concepts

- Assignment: A specific identifier used to categorize the customer for reporting purposes within SAP.
- Cost Center: An organizational unit within the SAP system that tracks where costs are incurred for this customer.
- Profit Center: An organizational unit that tracks the profitability and financial performance associated with this customer.
- Read-Only: A security and data integrity setting that allows users to view information without the ability to modify it directly in the interface.

1.4 Business Value

This feature centralizes critical financial metadata, reducing the time spent switching between the ERP and other financial systems. By surfacing SAP-specific reporting codes directly on the customer profile, we improve operational efficiency, minimize manual data lookups, and ensure that all team members are viewing consistent, accurate financial classifications for every customer.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - Settings Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Settings Card is a read-only information panel located within the Customer Detail page. Its purpose is to provide a quick, at-a-glance summary of specific business classifications and tax configurations assigned to a customer. This component ensures that staff can easily verify a customer's status without needing to edit or modify the underlying data.

1.2 Step-by-Step Flow

1. Data Retrieval: The system fetches the specific configuration profile associated with the selected customer.
2. Wholesale Verification: The system checks if the customer is classified as a wholesale buyer and displays "Yes" or "No" accordingly.
3. Franchise Verification: The system checks if the customer is a franchise store owner and displays "Yes" or "No" accordingly.
4. Tax Status Display: The system retrieves and displays the current service tax status (e.g., whether tax is always applied) for that specific customer.
5. Display: All information is presented in a clean, read-only format within the Customer Detail page.

1.3 Key Concepts

- Read-Only: Information is displayed for viewing purposes only; it cannot be changed directly from this specific card.
- Wholesale Customer: A business classification used to identify customers who purchase goods in bulk, often qualifying for different pricing or terms.
- Franchise Store Owner: A classification identifying if the customer operates as part of a franchise network.
- Service Tax Status: A label indicating the specific tax rules or requirements that apply to the customer’s transactions.

1.4 Business Value

This feature improves operational efficiency by centralizing critical customer profile information in one location. By providing clear, immediate visibility into a customer's wholesale status, franchise affiliation, and tax requirements, staff can make informed decisions during customer interactions and order processing without having to search through multiple screens or records.

BUSINESS REQUIREMENTS DOCUMENT

Customer Detail Page - Details Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Details Card is a dedicated component within the Lumi ERP system designed to provide a comprehensive, at-a-glance view of a customer's profile. This component acts as a centralized information hub, displaying all essential identity, contact, and professional data in a clean, organized layout. To ensure data integrity, all information presented in this card is strictly read-only, meaning it is intended for viewing purposes rather than editing.

1.2 Step-by-Step Flow

The component organizes customer information into four logical sections to ensure clarity:

1. Identity Section: Displays the core identifiers, including the customer's name, unique customer code, and national ID (KTP).
2. Contact Section: Shows communication and location details, specifically the phone number, email address, physical address, and area/region.
3. Professional/Personal Section: Provides background context, including the customer's company, occupation, gender, and birthdate.
4. Metadata Section: Displays administrative tracking information, including the assigned salesperson, the store where the customer was registered, and any additional notes.

1.3 Key Concepts

- Read-Only Display: A design approach where information is presented for reference only, preventing accidental changes to sensitive customer records.
- Data Placeholder: A fallback mechanism where the system displays a dash ("-") if a specific piece of information is missing, ensuring the interface remains clean and readable.
- Categorized Layout: The grouping of related data points (Identity, Contact, Professional, and Metadata) to help users quickly locate specific information without scanning the entire page.

1.4 Business Value

This feature improves operational efficiency by providing staff with a reliable, "single source of truth" for customer information. By consolidating scattered data points into one structured view, it reduces the time employees spend searching for details across different screens. Furthermore, the read-only nature of the component protects critical customer data from unauthorized or accidental modifications, supporting better data governance and accuracy across the ERP platform.

BUSINESS REQUIREMENTS DOCUMENT

Customer Add Wholesale Page - Details Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Customer Details Card" is a central component of the Wholesale Customer registration page. It provides a structured form for users to input and manage essential information about a new wholesale customer, including their identification, primary contact details, and banking information. The component ensures data quality by performing real-time validation on critical fields.

1.2 Step-by-Step Flow

1. Customer Identification: The user enters the customer's basic profile information, including their name (required), customer code, phone number, email address, national ID (KTP), regional area, and any additional notes.
2. Contact Information: The user provides specific details for the primary contact person, including their full name, phone number, email, job position, department, region, country (via a dropdown menu), and physical address.
3. Banking Details: The user enters the customer's banking information into a dedicated text area.
4. Real-Time Validation: As the user types, the system automatically checks the data. If the customer name is missing or if an email address (for either the customer or the contact person) is entered in an incorrect format, the system immediately displays an error message to guide the user.

1.3 Key Concepts

- Data Validation: A built-in safety check that ensures required fields are filled and that email addresses follow the correct format before the form is submitted.
- State Management: The system’s ability to "remember" and track all the information entered into the form fields in real-time.
- Input Fields: Standard text boxes and dropdown menus used to capture specific pieces of information, such as names, codes, and locations.
- Text Area: A larger, multi-line input box designed for longer entries, such as general notes or detailed banking instructions.

1.4 Business Value

- Data Accuracy: By enforcing required fields and validating email formats, the system prevents incomplete or incorrect data from entering the database, reducing administrative cleanup later.
- Operational Efficiency: Consolidating customer, contact, and banking information into a single, organized card streamlines the onboarding process for new wholesale accounts.
-

User Experience: Real-time feedback allows users to correct mistakes immediately while they are still filling out the form, rather than waiting until the end of the process to discover errors.

BUSINESS REQUIREMENTS DOCUMENT

Customer Add Wholesale Page - Tax Info Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Tax Information section is a new component within the wholesale customer registration form. Its purpose is to allow users to accurately capture and record essential Indonesian tax identification numbers for business customers. The system includes built-in validation to ensure that the data entered meets the required format standards, helping to reduce errors during the onboarding process.

1.2 Step-by-Step Flow

1. The user navigates to the Tax Information section of the wholesale customer registration form.
2. The user enters the customer's NPWP (Taxpayer Registration Number) into the designated field.
3. As the user types, the system automatically checks the NPWP format to ensure it contains the correct number of digits. If the format is incorrect, an error message appears immediately.
4. The user enters the customer's NPPKP (Taxable Entrepreneur Number) into the provided field.
5. The user enters the customer's NITKU (Business Activity Location Tax Number) into the final field.
6. The system maintains these entries as part of the customer's profile data for submission.

1.3 Key Concepts

- NPWP: The primary Taxpayer Registration Number used in Indonesia to identify a business for tax purposes.
- NPPKP: The Taxable Entrepreneur Number, required for businesses that are registered to collect and pay Value Added Tax (VAT).
- NITKU: The Business Activity Location Tax Number, used to identify specific business locations for tax reporting.
- Real-time Validation: A feature that checks the accuracy of the data as the user types, providing instant feedback so corrections can be made before the form is submitted.

1.4 Business Value

- Data Accuracy: By enforcing specific formatting rules for tax numbers, the system prevents common data entry mistakes, ensuring that tax records are reliable and compliant.
- Efficiency: Real-time validation saves time by alerting the user to errors immediately, rather than waiting until the end of the registration process to flag issues.
- Regulatory Compliance: Capturing these specific tax identifiers is essential for wholesale operations in Indonesia, ensuring the business remains compliant with local tax reporting requirements.

BUSINESS REQUIREMENTS DOCUMENT

Customer Add Wholesale Page - Customer Grup

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Customer Group" feature is a new component designed for the Wholesale Customer Add page within the Lumi ERP. It allows users to categorize wholesale customers by assigning them to specific groups. The feature is designed for efficiency, enabling users to select an existing group from a list or create a brand-new group on the fly without leaving the page.

1.2 Step-by-Step Flow

1. Selection: The user views the "Customer Group" section and uses a dropdown menu to select an existing group for the customer.
2. Validation: The system checks that a valid group has been selected. If no group is chosen, the system prompts the user to make a selection.
3. Creation (Optional): If the desired group does not exist, the user clicks the "+ New Group" button.
4. Modal Interaction: A pop-up window appears, allowing the user to enter a name for the new group and save it.
5. Automatic Update: Once the new group is saved, the pop-up closes, and the new group is automatically selected in the main dropdown menu, allowing the user to continue their work without interruption.

1.3 Key Concepts

- Customer Group: A classification label used to organize wholesale customers, helping businesses manage pricing, discounts, or reporting by category.
- Inline Creation: The ability to add new data (like a new group) directly within the current screen, preventing the user from having to navigate away to a different settings page.
- Validation: An automated check that ensures required information is provided before the form can be submitted, preventing incomplete data from entering the system.

1.4 Business Value

This feature streamlines the wholesale onboarding process by reducing administrative friction. By allowing users to create new customer groups directly within the "Add Customer" workflow, we eliminate the need for context switching. This saves time, reduces manual errors, and ensures that customer data is consistently categorized, which is essential for accurate wholesale reporting and management.

BUSINESS REQUIREMENTS DOCUMENT

Customer Add Wholesale Page - Addresses Card

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Addresses Card" is a component within the wholesale customer profile page that allows users to manage multiple contact and location details. It provides a clean, organized table to view all saved addresses and a dedicated interface to add new ones, ensuring that customer contact information is accurate and easily accessible.

1.2 Step-by-Step Flow

1. View Addresses: When a user visits the wholesale customer page, they see an "Addresses" section containing a table. If no addresses have been added yet, the table displays a message indicating that it is currently empty.
2. Initiate Addition: To add a new location, the user clicks the "Add Address" button.
3. Enter Details: A pop-up window (modal) appears, allowing the user to input the address type, primary and secondary phone numbers, fax number, and specify if the location serves as the "Main" or "Shipping" address.
4. Validation: As the user types, the system checks the information in real-time. For example, it ensures the primary phone number meets the minimum length requirement.
5. Save and Update: Once the user saves the information, the pop-up closes, and the new address immediately appears as a new row in the main table on the customer page.

1.3 Key Concepts

- Addresses Table: A structured list that displays all saved locations, including contact numbers and specific designations like "Main" or "Shipping."
- Address Modal: A focused input form that appears over the main page, keeping the user's workflow contained and preventing navigation away from the customer profile.
- Real-time Validation: A feature that checks data quality (such as phone number length) while the user is typing, providing immediate feedback to prevent errors before the information is saved.
- Address Designation: Simple checkboxes that allow users to quickly flag an address for specific business purposes, such as identifying it as the primary contact point or the default shipping destination.

1.4 Business Value

- Data Accuracy: By using real-time validation, the system prevents incomplete or incorrectly formatted contact information from entering the database.
- Operational Efficiency: Staff can quickly manage multiple customer locations in one place without needing to navigate to different screens or complex menus.
-

Improved Customer Service: Having clear, categorized address information (Main vs. Shipping) ensures that orders and communications are directed to the correct locations, reducing shipping errors and communication delays.

BUSINESS REQUIREMENTS DOCUMENT

Customer Add Wholesale Page - Settings Card

Prepared by Kolosal AI

Version	Date	Status	Classification
1.0	September 22, 2026	Draft	Internal

1. Frontend

1.1 Overview

The Wholesale Settings Card is a configuration component within the "Add Wholesale Customer" page. It allows users to define specific financial and operational rules for wholesale customers, such as credit limits, payment terms, and accounting preferences. The card is designed with sensible defaults to streamline the setup process while ensuring all numeric inputs remain valid (non-negative).

1.2 Step-by-Step Flow

1. Credit Configuration: Users enter the allowed payment duration (in days), the maximum credit limit, and the grace period for overdue payments.
2. Pricing and Tax Selection: Users select the appropriate currency, pricing list, and sales tax rate from predefined options.
3. Accounting Setup: Users assign specific accounts for invoices, credit notes, down payments, and deposits to ensure financial data is categorized correctly.
4. Operational Toggles: Users use checkboxes to identify if the customer acts as a card/QRIS provider or an insurance provider, and to toggle whether tax details should appear on printed sales invoices.

1.3 Key Concepts

- Credit Terms: The specific timeframe allowed for a customer to complete their payment.
- Overdue Limit: A defined grace period before a payment is officially flagged as late.
- Accounting Accounts: Pre-configured categories that ensure financial transactions (like invoices or deposits) are recorded in the correct ledger.
- Defaults: Pre-selected values (such as Indonesian Rupiah for currency) that speed up data entry while remaining fully editable.
- Validation: A built-in safety feature that prevents users from entering negative numbers in fields where only positive values are logical.

1.4 Business Value

This feature centralizes the complex financial settings required for wholesale relationships into one intuitive interface. By providing clear, pre-filled defaults and validation, it reduces manual data entry errors and ensures that every wholesale customer is set up with consistent accounting and credit policies, ultimately leading to more accurate financial reporting and smoother payment collection processes.

BUSINESS REQUIREMENTS DOCUMENT

Customer Add Wholesale Page - Data Mapping

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Data Mapping section is a new component within the Wholesale Customer registration form. Its primary purpose is to ensure that every new wholesale customer is correctly linked to an internal salesperson. By requiring this assignment at the point of entry, the system maintains accurate records for sales tracking and account management.

1.2 Step-by-Step Flow

1. The user navigates to the "Data Mapping" section of the Wholesale Customer Add form.
2. The user interacts with the "Salesperson" dropdown menu to select the appropriate representative from the list.
3. As the user makes a selection, the system immediately checks that a valid salesperson has been chosen.
4. If the user attempts to leave the field blank, the system displays a validation error message indicating that the salesperson is a required field.
5. Once the form is completed and submitted, the selected salesperson information is sent to the system to finalize the customer record.

1.3 Key Concepts

- Data Mapping: The process of linking specific customer information to internal system records, in this case, assigning a customer to a specific staff member.
- Validation: An automated check that ensures required information is provided before the form can be successfully processed.
- Required Field: A mandatory data point (marked with an asterisk) that must be filled out to ensure the integrity of the customer record.

1.4 Business Value

- Improved Accountability: By mandating a salesperson assignment, the business ensures that every wholesale account has a clear point of contact for sales and support.
- Data Integrity: Real-time validation prevents incomplete records from entering the system, reducing the need for manual data cleanup later.
- Streamlined Workflow: Integrating this assignment directly into the "Add Customer" process saves time by eliminating the need for secondary administrative steps to assign accounts after they are created.

Customer Products Filter Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Products Filter component is a new tool designed to help you quickly find specific information within the customer products list. Instead of scrolling through a long list of data, you can now narrow down your view by selecting specific criteria. This feature provides a clean, user-friendly interface to refine your search results before updating the table.

1.2 Step-by-Step Flow

1. Select Criteria: You choose your desired options from three dropdown menus: Membership Tier, Vehicle, and Source. You can use any combination of these filters, or leave them blank if you wish to see all results.
2. Initiate Search: Once you have selected your preferred filters, click the "Search" button.
3. Update Results: The system takes your selected criteria and automatically refreshes the product table to display only the items that match your choices.

1.3 Key Concepts

- Membership Tier: A category filter that allows you to view products associated with specific customer membership levels.
- Vehicle: A category filter that allows you to isolate products related to a specific vehicle type.
- Source: A category filter that allows you to narrow down products based on their origin or acquisition channel.
- Filter Refresh: The action of updating the table data based on your current selections, ensuring you only see the information relevant to your search.

1.4 Business Value

This feature significantly improves efficiency by reducing the time spent manually searching for specific customer products. By allowing users to filter by membership, vehicle, and source, the system enables more precise data analysis and faster decision-making. It transforms a large, overwhelming list into a manageable set of relevant information, directly supporting better customer service and inventory management workflows.

Customer Detail Page - Retail Purchasing

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Retail Purchasing feature provides a clear, organized view of a customer's purchasing history within the Lumi ERP system. It allows users to navigate from a customer's profile to a detailed list of their transactions, where they can review specific purchase documents, track their status, and verify key transaction details at a glance.

1.2 Step-by-Step Flow

1. Accessing the List: From the Customer Detail page, the user clicks the "Show Purchasing Details" button to navigate to the full list of retail purchases for that specific customer.
2. Viewing the Table: The system displays a table containing all relevant purchase records.
3. Reviewing Transaction Details: Each row in the table provides specific information, including the document number, the date and time of the purchase, the total amount, the store location, the staff member who created the record, and the current status of the transaction.
4. Navigating to Documents: If a user needs more information on a specific transaction, they can click the blue, highlighted Document Number to be taken directly to that specific document's detail page.

1.3 Key Concepts

- Document Number: A unique identifier for a purchase that acts as a direct link to the full document details.
- Status Badge: A visual indicator showing the progress of a purchase. "Draft" items appear in grey, while "Completed" items are highlighted in green for quick identification.
- Currency Formatting: Financial amounts are displayed using a standard format (using dots for thousands and commas for decimals) to ensure consistency and readability.
- Read-Only Columns: Most information in the table (such as date, store, and creator) is displayed for reference purposes only, ensuring data integrity.

1.4 Business Value

This feature improves operational efficiency by centralizing customer purchase data. By providing a clean, searchable, and navigable table, staff can quickly resolve customer inquiries regarding past purchases, verify transaction statuses without manual searching, and easily drill down into specific documents when necessary. This reduces the time spent on administrative tasks and provides a better experience for both the staff and the customer.

Customer Add Vehicle Dropdown Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Customer Add Vehicle Dropdown component is a smart form tool designed to streamline how users add vehicles to the system. It acts as a "master control" for vehicle data entry: by selecting a vehicle type (such as a car, motorcycle, or heavy equipment), the form automatically adjusts itself to show only the relevant fields for that specific category. This ensures that users are never presented with unnecessary information, keeping the data entry process clean and error-free.

1.2 Step-by-Step Flow

1. Select Vehicle Type: The user begins by choosing a vehicle type from a dropdown menu. This is the primary action that dictates the rest of the form's behavior.
2. Automatic Reset: Whenever the vehicle type is changed, the system automatically clears the existing entries for Make, Model, and Category to ensure data consistency.
3. Dynamic Field Updates: The system reloads the available options for "Vehicle Make" based on the new type selected.
4. Conditional Display: If "Heavy Equipment" is selected, the form expands to reveal specialized fields (Hour Meter, Engine Power, Engine Brand, Engine Model, and Engine Year).
5. Data Cleanup: If the user switches away from "Heavy Equipment" to a standard vehicle type, the system automatically hides and clears the specialized heavy equipment fields, ensuring that irrelevant data is not saved.

1.3 Key Concepts

- Conditional Rendering: The practice of showing or hiding specific form fields based on the user's previous selections, ensuring the interface remains uncluttered.
- Dependent Fields: Form inputs that rely on a parent selection; for example, the "Vehicle Make" options change automatically based on the "Vehicle Type" chosen.
- Data Integrity: The automated clearing of fields during a type change prevents "orphaned" data (e.g., keeping engine details for a vehicle type that doesn't support them).

1.4 Business Value

- Improved Data Quality: By dynamically showing or hiding fields, the system prevents users from entering incorrect or irrelevant information, leading to cleaner records.
- Enhanced User Experience: Users save time by only interacting with fields that are relevant to the specific vehicle they are adding, reducing cognitive load and form complexity.

– Standardization: Because this component is used across all areas of the application where vehicles are created or edited, it ensures a consistent experience and uniform data collection across the entire platform.

2. Logic

2.1 Overview

The "Add Vehicle" component includes a specialized tracking field for heavy equipment known as the "Hour Meter." This feature allows users to record the operational usage of a piece of equipment, ensuring that maintenance schedules and usage logs remain accurate. The system includes built-in safeguards to ensure that the data entered is valid and formatted correctly before it is saved to the customer's profile.

2.2 Step-by-Step Flow

1. Input Entry: The user enters the current hour meter reading into the designated field.
2. Validation Check: As the user enters the data, the system immediately checks the input against three rules:

* The value must be zero or greater (negative numbers are not allowed).

* The value must not have more than two decimal places (e.g., 100.55 is acceptable, but 100.555 is not).

* The field must contain a value, as it is a required entry.

3. Error Handling: If the input violates any of these rules, the system rejects the entry and notifies the user of the specific error.
4. Data Sync: If the input is valid, the system accepts the value and updates the vehicle record to reflect the new hour meter reading.

2.3 Key Concepts

– Hour Meter: A measurement tool used for heavy equipment that tracks total operational time, similar to an odometer in a car.

– Data Validation: An automated check performed by the software to ensure that the information entered by a user meets specific business requirements before it is processed.

– Decimal Precision: A constraint that limits how many digits can be placed after the decimal point, ensuring consistency in how usage data is recorded.

2.4 Business Value

By standardizing how hour meter data is captured, this feature helps maintain high data integrity for your heavy equipment fleet. Accurate hour tracking is essential for scheduling preventative maintenance, calculating equip-

ment depreciation, and ensuring that service intervals are met, which ultimately reduces the risk of unexpected equipment failure and costly downtime.

BUSINESS REQUIREMENTS DOCUMENT

GET /api/accounts

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Logic

1.1 Overview

This feature provides a way for the system to retrieve a list of "Chart of Accounts" records. It is designed specifically to populate dropdown menus in the application—such as those used when setting up supplier payment or invoice accounts. The system ensures that only active, valid accounts belonging to the user's specific company are displayed, keeping the data relevant and secure.

1.2 Step-by-Step Flow

1. Authentication: The system verifies that the user is logged in. If the user is not authenticated, the request is rejected.
2. Parameter Validation: The system checks any provided search terms, account types, or pagination settings (limit and offset) to ensure they are formatted correctly.
3. Data Retrieval: The system searches the database for accounts that match the user's company, are marked as "active," and are eligible for transaction posting.
4. Filtering: If a search term or specific account type was provided, the system narrows down the results accordingly.
5. Response: The system returns the list of matching accounts (including their ID, code, name, and type) or provides an error message if the request could not be processed.

1.3 Key Concepts

- Chart of Accounts: The master list of financial accounts used by a company to categorize transactions.
- Postable Accounts: Accounts that are currently eligible to have financial transactions recorded against them.
- Pagination: A method of breaking a large list of results into smaller, manageable chunks using "limit" (how many to show) and "offset" (where to start in the list).
- Scoped Data: A security measure ensuring that users can only view and interact with account data that belongs to their own company.

1.4 Business Value

This feature streamlines the user experience by providing a reliable, filtered list of accounts directly within the interface. By automating the retrieval of these lists, it reduces manual data entry errors and ensures that users only select valid, active accounts when configuring supplier settings or processing invoices. This maintains the integrity of the company's financial records.

2. Data

2.1 Overview

The `GET /api/accounts` feature provides a way for the system to retrieve a list of Chart of Accounts records. This list is specifically designed to populate dropdown menus in the Supplier Form, such as those used for selecting invoice, credit note, or deposit accounts. The feature ensures that users only see accounts that are relevant to their specific company and are currently eligible for financial transactions.

2.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to fetch account data, including optional filters for searching by name/code, filtering by account type, or adjusting the number of results shown (pagination).
2. Validation: The system checks that the requested pagination settings (how many items to show and where to start) are valid numbers.
3. Data Filtering: The system identifies the accounts belonging to the user's company. It automatically excludes any accounts that are inactive or restricted from being used in transactions.
4. Applying User Criteria: If the user provided a search term or a specific account type, the system narrows down the list to match those requirements.
5. Response: The system returns the final list of eligible accounts to the user. If the request is invalid, the user is not logged in, or a server error occurs, the system provides an appropriate error message.

2.3 Key Concepts

- Chart of Accounts: The master list of financial accounts used by a company to categorize transactions.
- Postable: A status indicating that an account is currently eligible to have financial transactions recorded against it.
- Scoped Data: A security measure ensuring that users can only access and view account information belonging to their own company.
- Pagination: A method of breaking a large list of data into smaller, manageable chunks (using "limit" and "offset") to improve performance and usability.
- Search/Filter: Tools that allow users to quickly find specific accounts by typing a name or code, or by selecting a specific category of account.

2.4 Business Value

This feature streamlines the data entry process for accounting staff by providing a clean, filtered list of valid accounts directly within the Supplier Form. By automatically hiding inactive or non-postable accounts, it reduces the risk of manual entry errors and ensures that financial data remains accurate and compliant with company accounting standards.

BUSINESS REQUIREMENTS DOCUMENT

New Stock Opname - Autofill Modal

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The "Autofill Stock Opname" modal is a productivity tool designed to help users quickly populate their stock-taking (opname) forms. Instead of manually adding items one by one, users can define specific criteria—such as product category, brand, or supplier—to automatically pull a list of relevant products into their current stock opname session.

1.2 Step-by-Step Flow

1. Open the Modal: The user initiates the autofill process from the New Stock Opname form.
2. Define Filters: The user selects specific criteria to narrow down the product list, including:

* Product Type, Brand, and Supplier: Using dropdown menus to filter by source or classification.

* Product Info: Selecting a category (e.g., Item Category, Business Unit, or Car Type) and entering a specific starting value.

3. Set Display Preferences: The user chooses how the results should be sorted (by SKU or Name) and whether to include items currently showing zero stock.
4. Define Movement Criteria: The user specifies a timeframe (in days) to filter products based on recent activity.
5. Validation: The system checks that the "Movement Days" entry is a valid, non-negative number.
6. Execute and Populate: Upon clicking "Save," the system retrieves the matching products and automatically adds them to the main Stock Opname form, closing the modal in the process.
7. Cancel: If the user chooses to cancel, all selections are discarded, and the user is returned to the main form without any changes.

1.3 Key Concepts

- Stock Opname: The process of verifying physical inventory against system records.
- Autofill: A feature that automates data entry by fetching a group of items based on user-defined rules rather than manual selection.
- Movement Days: A filter that allows users to focus on items that have had activity (sales, receipts, or adjustments) within a specific recent period.
- Zero Stock Toggle: A setting that allows users to decide if they want to include items that are currently out of stock in their inventory count.

1.4 Business Value

-

Efficiency: Significantly reduces the time spent manually searching for and adding individual products to a stock-taking list.

- Accuracy: Minimizes human error by ensuring that the list of products is generated based on consistent, system-defined criteria.
- Flexibility: Provides granular control over which inventory items are included in a count, allowing teams to perform targeted stock checks (e.g., by brand or by recent movement) rather than always performing a full-warehouse count.

2. Logic

2.1 Overview

The "Stock Opname Autofill" feature is designed to simplify the inventory counting process by allowing users to quickly pull a specific list of products into their stock-taking sheet. Instead of manually searching for and adding items one by one, users can define specific criteria—such as product category, brand, or supplier—and the system will automatically generate a list of relevant products to be counted.

2.2 Step-by-Step Flow

1. Define Criteria: The user selects specific filters in the modal, such as the product type, brand, or supplier.
2. Refine Search: The user provides additional details, such as specific keywords or product information, to narrow down the list further.
3. Set Preferences: The user chooses how to sort the results and decides whether to include items that currently have zero stock or items based on their recent movement history (e.g., items that have moved in the last 30 days).
4. Data Processing: The system collects all these selections and sends them as a request to the inventory database.
5. Autofill Execution: The system retrieves the matching products and automatically populates the stock opname sheet with the filtered list.

2.3 Key Concepts

- Stock Opname: The process of physically counting inventory to ensure the actual stock matches the system records.
- Autofill Criteria: The set of filters (like brand or supplier) used to narrow down which products need to be counted.
-

Movement Days: A filter that identifies products based on how recently they were sold or moved, helping users focus on active inventory.

- Zero Stock Inclusion: A toggle that allows users to decide if they want to include items that are currently out of stock in their count.

2.4 Business Value

- Increased Efficiency: Reduces the time spent manually searching for and adding products to a stock-taking list.
- Improved Accuracy: Minimizes human error by ensuring the correct subset of products is pulled based on predefined business rules.
- Better Inventory Control: Allows staff to perform targeted stock counts (e.g., counting only high-movement items or specific brands), leading to more frequent and manageable inventory audits.

BUSINESS REQUIREMENTS DOCUMENT

Account Dropdown List Response JSON Schema

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Data

1.1 Overview

This feature provides a standardized way for the system to retrieve and display a list of accounts in a dropdown menu. It ensures that when a user needs to select an account (for example, when recording a transaction), they only see relevant, active, and valid accounts that belong to their specific company.

1.2 Step-by-Step Flow

1. Request Initiation: The system receives a request to populate an account dropdown menu. It automatically identifies the user's company to ensure data privacy.
2. Data Filtering: The system searches the Chart of Accounts database, applying strict rules to include only "active" accounts that are designated as "posting accounts" (accounts that can actually receive transactions).
3. Optional Refinement: If the user has typed a search term or selected a specific account category, the system narrows the results to match those criteria.
4. Sorting: The resulting list is organized numerically by the account code to ensure a consistent and predictable order.
5. Formatting: The system packages the filtered data into a clean, structured format that the user interface can easily read and display as a dropdown list.

1.3 Key Concepts

- Posting Account: A specific type of account in the ledger that is eligible to have financial transactions recorded against it.
- Company Scoping: A security measure that ensures users only see financial data belonging to their own organization.
- Active Status: A filter that hides archived or discontinued accounts, preventing users from selecting outdated options.
- Search/Filter Logic: The ability to quickly find specific accounts by typing part of a name or code, or by narrowing down by account classification.

1.4 Business Value

- Data Integrity: By automatically filtering for "posting accounts," the system prevents users from accidentally selecting header or summary accounts that shouldn't receive direct entries.
- Improved User Experience: Users can find the correct account faster through search and filtering, reducing manual effort and potential selection errors.
- Consistency: Standardizing the response format ensures that dropdown menus behave the same way across the entire application, making the software easier to maintain and update.

BUSINESS REQUIREMENTS DOCUMENT

Areas Menu Tab

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Areas Menu Tab is a navigation component designed to help users easily move between different administrative levels within the Lumi ERP system. It acts as a central control bar on the Areas page, allowing users to quickly switch their view between Provinces, Regencies/Municipalities, Districts, and Villages.

1.2 Step-by-Step Flow

1. The user accesses the Areas page, where the menu tab is displayed.
2. The user selects one of the four available administrative categories: Province, Regency/Municipality, District, or Village.
3. Upon clicking the desired category, the system immediately redirects the user to the corresponding list page for that specific administrative level.

1.3 Key Concepts

- Administrative Levels: The hierarchical structure of geographic or political regions (Province, Regency/Municipality, District, and Village) managed within the ERP.
- Navigation Menu: A persistent interface element that allows users to jump between related sections of the application without needing to return to a main dashboard.
- Context Switching: The ability for a user to change their current focus area (e.g., moving from viewing a list of Provinces to a list of Districts) with a single click.

1.4 Business Value

This feature improves user efficiency by providing a clear, consistent, and accessible way to navigate complex geographic data. By grouping these administrative levels into a single menu, we reduce the number of clicks required to perform tasks, minimize navigation errors, and ensure that users can quickly find the specific administrative data they need to manage.

BUSINESS REQUIREMENTS DOCUMENT

Sales Invoice Detail - Company Navigation Tab Component

Prepared by Kolosal AI

Version 1.0 **Date** September 22, 2026 **Status** Draft **Classification** Internal

1. Frontend

1.1 Overview

The Sales Invoice Navigation Tabs feature provides a clean, organized way for users to switch between different categories of information within a specific sales invoice. Instead of cluttering the screen with all invoice data at once, this component acts as a menu, allowing users to focus on specific areas like financial journals, delivery status, or historical changes with a single click.

1.2 Step-by-Step Flow

1. The user opens a specific Sales Invoice record.
2. The navigation bar displays five distinct tabs: Details, Journals, Deliveries / Payments, Returns, and Changes.
3. The system automatically highlights the tab corresponding to the information currently being viewed.
4. When the user clicks on a different tab, the system instantly updates the main view to display the content associated with that selection.
5. As the user navigates, the system maintains the context of the specific invoice they are currently reviewing.

1.3 Key Concepts

- Navigation Tabs: A menu interface that allows users to toggle between different views of the same record without leaving the page.
- Active State: A visual indicator (such as highlighting or underlining) that tells the user which section of the invoice they are currently looking at.
- Contextual Routing: The ability of the system to remember which invoice is open while switching between different data categories (like Journals or Returns).

1.4 Business Value

This feature improves user efficiency by reducing information overload. By grouping complex invoice data into logical, easy-to-access sections, users can find the specific information they need—such as payment status or audit trails—much faster. This streamlined layout minimizes the time spent searching for data, leading to a more intuitive and productive experience for finance teams managing high volumes of invoices.
